What I have done, when not having other means, is to swing a line weighted at its end in a circle having its plane bisecting the target with the direction of travel of the weighted end such that the weighted end is traveling upward when closest to the target. (some people find that the other direction is more easy to control) Letting go of the line as the weighted end comes up will tend to send the weighted end towards the target. One may practice out in the open first to get a feel of when to let go. The remainder of the line needs to be arranged so that it will follow the weighted end without a snag. Be sure to have a long enough line and attach the far end!
As others have said, use string for the line.
Let us know where you are.

You'd be amazed at how handy a 14-year old kid can be for such tasks.
I bought one of those rope chain-saws to trim out some limbs for my
G5RV. Damn thing beat me to death tossing that sandbag hacky-sack up in
the air. Kids thought it was something fun to do.
For the antenna I used some large square nuts (like they use on utility
poles) and fishing line for the tossing process. A good kid can get
this on target 50 feet in the air with no sweat even with an overhand
throw.

I know this is not an antenna question but I thought this would be a good place to ask anyway.

A house close by us was damaged badly by a fire caused by a lightning strike to its gas meter, (strange) Should those things be grounded or are they already grounded? I looked at the house and the gas meter is in a low spot to the rear of the house with pine trees close by and a swiming pool near also.

Hi,

I ordered a wellbrook ALA-330 magnetic loop antenna (mainly suited for indoor listening purposes in the HF bands). The system comes with a BNC connector.

I'd like to know how to feed such antenna and link it to my RTX equipped with a PL connector ?

(I usually use a G5RV or a longwire 40m long but this new kind of antenna is a complete mystery for me, excepting I hope it will help me to solve my QRM problem generated by electrical devices).

I'd like to use a coaxial RG58 to feed this mag loop but I know that is this kind of cable the current passes through the center wire and the magnetic field moves around it (between the wire and the braid). In order there is current in my RG58 cable there must have a difference of potential that is materialized by the electric field of this cable.
But if I well understood how my mag loop works, it does not use the electric field. So how to proceed ? Do you understand my trouble ?

So there are two simple question :
- How to convert my BNC to PL connector ? (Simply by cutting the BNC and placing in place a male PL ?)
- Can I use a RG58 to feed my aerial ? (as we do most of the time when 50 omhs are required)

Thanks for comments

dj:
I suspect that this issue is covered in whatever gas code your community uses. I'd look there for an answer to this question. Gas codes are usually vigorously enforced so I suspect that you won't find a problem with your installation.

Looking in my junkbox I have several varieties of PL to BNC and BNC to PL converters. Not sure where I got them, but they do make them. Sounds like that is what you need. Or, just cut off the wrong connector and connect the right connector.
>- Can I use a RG58 to feed my aerial ? (as we do most of the time when
>50 omhs are required)

Sure. If your antenna impedance is around 50 ohms. Even if its not, for rx it is not critical. In an antenna system you have a transmission line (rg58) and an antenna. The antenna does the receiving and the transmission line does not. You seem to be concerned with interaction beween your mag loop and line. If this is the case, then other types of transmission line will also be effected

Hi,

In one of my QTH I have enough place in the garden to install a multiband dipole of about 33m (100') ot twice that length (but the first option is less visible and more pratical for me). I'm on top of hills with an open field 360 deg around.

So I would like to replace with 40m long wire by something more efficient (forget currently the beam and vertical). I have the choice to install a G5RV with a symetric feedline + coax RG58 or a W3DZZ feeded with a simple coax RG58. Knowing these models are very appreciated in the US, I post my question on this forum.

But from your experience, as my first objective is DX with few local activities, what can I install : the G5RV or the W3DZZ ?

Hints : According the theory, the second solution seems better : one type of feedline, easy to use as inverted V in necessary, traps allow to be resonant on L/2 on various bands and even 3/2L on 20m, 5/2 on 15m, etc.
As traps quality if very important in this model of dipole, do you know a good manufacturers of W3DZZ, famous of the quality of its antennas ?

Thanks.

Thierry

Hi fellows;

I used for more then a year an old GP-antenna for CB on 17 and 12m. I removed the ridiculous coil, on PCB, in the feedpoint.
Then I shortened the antenna to the length of a quarter of a wavelengte for 12m. Made a coax-trap on an Ertalon coilform and put it on the top of the antenna with an adjustable wip for 17m. On the feed i made three quarter-wave radials for eash band sloped 135° from the antenna.
The best is to the antennafoot is isolate of the fiting point. Also use a good current-balun. That can be made by turning the coax just below feedpoint in coil form. A 10 turns (RG58) wil be sufficent. I worked the whole world (max 100W) with that antenna on both bands and it was only fit on an 12 feet aluminium tube in the backyard nearby a tree. I using now a dual band home made rotary dipole for these bands. The signals are beter. If you like to start slowly, a recommend a rotary triband dipole. I worked my firsth 275 DXCC on that antenna, VK0IR include.
To feed an antenna you beter use RG213 or beter. Loss is great on RG58 for long lengths.
For the lowbands i used longtime a 22m long wire. sloping from 8 to 4m and the last 4m vertical. A T-filter (2c and 1 L) at the feedpoint. An earthpin as close as possible to the feedpoint and T-tuner. And some wires over the lane as radials connected to the earthpoint. The use of a good currentbalun is needed. That antenna can be tuned for 40, 80 and 160m. On 80 i made XZ1N straight to a huged pile up after 2 time calling. (100W) and ZL8CI on 40m. I now using a vertical for 30 and 40m and inverted L for 80m. Both home made.
Most commercial baluns are good in the middle of there band wide but the low and high ends are bad. Beleve me, a balun for 1.8 to 30MHz does not exist. A car to drive 300km/h and pull 40 tons in a rally does not exist to. And multiband antennas from 40 (or even 80 or 160) to 10 (or 6m) ar not efficient for all the bands.(An log periodic is an exception). I take the rule of maximum 3 bands per antenna. The more bands on one antenna the less the effecienty on the bands.
To feed an antenna, for single band antennas you have the advantage the use very simple C-L tuning units. In stead of the heavy and noisy baluns.
So greeting from Belgium.

Hi guys - I am getting ready to build a loop.

Planing to feed it with 450 ohm line to an autotuner on the ground
and run all bands 160-10m.

My question is this:

Will 260 feet be an ideal length? It's going to be about 25-35 feet
high supported by trees.

It will probably not be exactly the same hieght all around. It will
definately not be square but some sort of odd shaped and
4 or 5 sided affair.

Does anyone else have experience with such real world loops
that can comment and/or give me any tips before I get started?

Thanks - AF4K

Source record: 135047

That loop should work out. General rule of thumb is to make the loop as large as possible for all band operation. For 160, the loop could be a little higher, like 50 ft or so but it will still work at 25 ft. You'll notice that as you go from 160 m toward 10 m, it will lose the overhead high angle pattern and have more low angle lobes which will be better for DX.

It will have less noise pickup than a vertical antenna.

On some bands, you might have a matching problem, it is hard to predict in advance. Adding some more feedline might help or you could build a wider range matching network, such as a double balanced network.

Make the installation such that it is easy to lower, such as using pulleys and ropes. This will allow you to lower it when ice storms threaten. Also, ensure you have a rapid disconnect means so that you can remove feedlines when thunderstorms are in the area.

Best of luck and keep us all informed of your experiences.

73s,

Evan

The antenna you're using is resonant at the top of your range. An antenna resonant in the middle of your range, tuned by your current antenna tuner, with twinlead as a feed, would probably do better.

Certainly, higher would be better, too.

Mike,

I totally agree with you about the name & address thing to, it takes to much time & personally I feel like I'm prying into a strangers life. I don't know of any other store that does this but unfortunately it their policy. It's especially annoying when you have 10-15 people in line & you have to ask for N & A, this makes people wait longer. Personally I would like to see it disapear quickly.

This has already happened in Daytona Beach FL. I use to buy lots of connectors and adapters. Just the other day I went in for two BNC connectors and a few communication speakers (the week before there were five speaks on the shelf). The other day they removed all components, parts and coax connectors (as well as audio connectors). I wanted 3 speakers and they were missing too. I went up to the salesperson to ask about the speakers. She looked at my phone on my belt and before I could get a word out she said "What Cell Phone Service plan do you have?" I said that was personal information but I'm very happy with my plan, where were the speakers that were on that shelf the other day and were are your BNC connectors that were on the wall? Her responce "there is not demand for those items anymore so we don't carry them".

True store, happened at the RadioShack in the Voluisa Mall, Daytona Beach, FL. Looks like I'll be taking a trip to AES in Orlando more often now.....

Hello Rich.

I have a home-brew all-solid-state transceiver for 160 metres only. It is about 23 years old.

The receiver front end consists of a two-coil, narrow-band, tunable, bandpass filter, covering the approx range 1.75 - 2.05 MHz. The antenna was usually a 160m, 3/8-wave, inverted-L. There were several high power medium and long-wave stations in the vicinity.

The two tuned circuits are top-capacitance coupled. Each of the tuned circuits is tuned with a varicap. The two varicaps are ganged together, both being contained in the usual small plastic package with three connecting wires. The varicaps are well matched having been designed for ganged operation.

Tuning over the band is done 'remotely' by a single DC potentiometer on the front panel. This occupies far less space than a two-gang variable capacitor. Furthermore, the problems associated with having the receiver tuned circuits at the front of the transceiver with the antenna coming in at the rear to the transmitter are entirely eliminated.

The transmit/receive VFO/RIT also uses a varicap. Hint: don't use a wire-wound pot in this application otherwise the VFO jumps between turns. Use a carbon or loaded-plastic pot.

I still have this transceiver but have not used it for about 10 years except for occasional checks. It has sentimental value.

Barring being struck by lightning, you have an excellent chance of success.

On the other hand there may not be any great advantage in locating a receiving tuner at the top of the mast. But nice to experiment with.

Hi Wayne,
I use a slingshot with a small lead weight and nylon fishing line (get the fluorescent red line if you can, since it's easier to see where it comes down). I wrap the line around a small can (like for baking soda), tap a tent stake into the ground, and put the can on top. A rubber band can keep the line in place until you're ready. I've had success with this cheap system. Look downrange before shooting to make sure the area is clear (don't want to clonk the XYL or the neighbor's cat), and shoot until you get the fishing line in a good spot. If it's not, untie the weight and rewind the line on the can. Once the location in the tree is OK, tie some light nylon cord to the weight end of the fishing line, wrap the knot in tape so the knot won't snag in the tree, and rewind the fishing line onto the can to pull the nylon cord through the tree and back to the original spot. Light nylon cord is used since the fishing line may not be strong enough for the rope or wire. Finally, tie the rope or wire to the nylon cord and pull it through the tree. 73 es GL,
Bill N3WK

Ok, I just want to have the most basic but useable antenna for shortwave broadcast in the 5MHz - 14 MHz range.

Can any of you offer a suggestion?

I have a fence (aluminum fence) that when I hook my radio to it, I get major gain, but plenty "other" noise.... what can help eliminate some of this noise? Or How should I go about making a better antenna?

Hi,

Politely tell them to put an "R" as in "Refused" in the First Name field and that's it. If they still insist, give your name as "Mickey Mouse" or Donald Duck". At that point they'll usually stop.

4713. Re: is/should natural gas meters be grounded?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-08 15:23:28 UTC
From: Roger Leone <arleoneSPAMBLOCK@inreach.com>
Message-ID: <wXJe9.765$Y07.207860828@news.inreach.com>
Source record: 135054

Here in Northern California gas meters/pipes are not considered grounded. This usually is a matter of concern when looking for a ground connection for our ham stations. We don't use gas pipes for grounds but water pipes are OK.

The explanation I have heard (with no direct knowledge to confirm) is that the meter may be connected to the mains via a flexible plastic pipe which is of course a non-conductor. And the mains have a small DC voltage on them for corrosion prevention.

As already mentioned, different areas have different methods. I just guessing, but I would think a direct hit by lightning would cause a problem for a gas meter whether grounded or not.

4714. AZ/EL Antennas with El-Cheapo Rotors

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-08 15:32:37 UTC
From: Jeff Breitner <zed-pappa-tango-romeo@rudn.com>
Message-ID: <unmrla6a577h54@corp.supernews.com>
Source record: 135057
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.space

I'm interested in creating an az/el antenna system with el-cheapo rotors (as opposed to dropping $600 for a Yaesu GX-5000). Researching, I've found hints that this has been done to some degree of success, but no one really goes into much detail about it.

While I'm pretty sure I can figure out how to make it work, I'm curious if anyone in the newsgroup has actually done this and what issues they have discovered. More importantly, do you find that this setup has shortcomings that in short-order would simply result in a dedicated amateur (and cost-conscious) scrapping the whole affair and buy the Yaesu anyway?

Thanks for your input.

I'm toying with some space saving antenna options. These ideas below just seem to fit my needs very well.

I mounted a pair of Iron Horse 6m mobile antennas as a vertical dipole, side-mounted from my tower and am very pleased with the results. The following three ideas are a result of this simple approach.

Would it be feasible to mount pairs of dipoles, for each band, horizontally on a common boom, in a log periodic looking arrangement, with a common feedline to a remote switch?

Would this arrangement provide beam-like characteristics? What kind of spacing would be required between dipoles?

Or would I be better off mounting them vertically as common rotatable dipoles with remote switching? Again what kind of space would be required vertically between dipole sets.?

The third concept I've had is making a star shaped base to mast mount and mounting vertical dipoles on each point, again remotely switched.

4716. Re: Question about ladder line and metal mast

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-08 15:47:23 UTC
From: Jeff Breitner <zed-pappa-tango-romeo@rudn.com>
Message-ID: <unmsh0rnaak821@corp.supernews.com>
Source record: 135058

I've always found that the best rule of thumb is a minimum of the inside spacing of the ladder line. I've never had any issues when I kept within that.

I've created stand-offs with old discarded Lexan, a blowtorch, a piece of pipe approximately the diameter of the mast and a hack saw.

Make sure the plastic you use is thick enough to do this without breaking under the weight of the feedline.

First, cut the Lexan into 8" strips about 3" wide.

Create a slit in one end of the Lexan that's wide enough for the ladder-line or twin lead to fit into. If you have true ladder-line, you can try to grip one conductor. The idea is that once the ladder line or twinlead is gripped in this slit, you'll use a bit of adheasive (silicone goop) or a tie-wrap to keep it inside the standoff.

On the other end, carefully heat the Lexan on one edge approximately 2-3" from the end. When the Lexan is soft, use your piece of pipe to mold the Lexan around the curvature of the pipe. This is the end that you're going to hose-clamp/tie-wrap/duct tape/whatever to the mast.

With the Lexan still warm and bendy, make a 90 degree bend at the point where the curvature flattens out. The direction doesn't matter, the idea is that this is the right angle away from the plane of the mast.

Let the plastic cool. It should be obvious how this works at this point. You can experiment with the lengths, widths and other assorted dimensions.

As usual, you're on your own if you do this. Be careful with the torch, the plastic, the fumes, your antennas and everything else for which I'm not responsible.

If you have questions, you can email me by decoding the phonetics of the email address, removing the hyphens and sending the the four letter addressee at the domain name.

Good luck.

Alan,

Like several people have stated, unless the antenna is pretty high, a single dipole will already be non directional. If you go for the two though, each of the dipoles will need to be a slightly different lengths from what a single dipole would be. Also, as somebody mentioned, if you make the two dipoles a different length from each other, you can get more bandwidth. I ran as EZ Neck program on crossed 75/80 meter dipoles, and got SWR less than 2 from 3.5 to 4 MHz. I had a 7MHz, 18 MHz, and 24 MHz antenna fed from a common feedline (@60 feeet), and it worked great. I used a balun. If you do this, you have to trim the lowest frequency antenna first.

take a wire, stick it in the antenna jack. thats about as basic as you can get.

i just use a piece of insulated wire about 25' long stuck in the jack and thrown under my bed, works fine for the big sw broadcasts. if you want more gain then make it longer and higher, but then you have to start worrying about what direction it is aimed. as you add gain in one direction you must lose in some other direction.

Hi Rick,

Have you tried M2?
http://www.m2inc.com
They have some upgrade parts for KLM's. Not sure if they have what you need.
If it's not on their website, maybe you can give them a call to find out where
you can get them.

Good Luck
Tom

The Radio Shack marketing executive (marketing moron) that was pushing this name and address deal (a few of the stores still ask for it) must have left RS.

I have now found that the Container Store (yes HQ in Texas) is now doing this same thing.
Care to take a bet this is where the Radio Shack executive ended up?

When I worked in the Dallas/Ft. Worth area (1980's) -- large telemarketers in that area were always "acquiring" new lists. I never found out if they legitimately acquired those RS lists.

Source record: 135065

Stuart,
A simple wire antenna is about as basic as you
can get. Make it as long as possible and as high
as possible. Height is more important than length.
Some of the noise you get with the fence may be
due to 'parts' of the fence moving/rubbing together.
If that's the case, the noise can be reduced by
stopping the movement. Depending on the kind of fence
it is, that may not be very practical, though. No
matter the antenna, you always hear more noise when
you hear more signals you want to hear (to some
extent).
Good luck, have fun...
'Doc

Source record: 135066

AF4K,
It should work okay on all but 160m and maybe
40m. For 160m 260 feet is going to be too short.
It may still be 'usable' but it won't be 'good'
by any means. On 40m it will be the second
harmonic for the antenna and that is almost always
not 'good'. But like on 160m it will be 'usable'.
Since the loop at 260 feet will only be resonant on
80m, you will have a non-resonant antenna on all
the other bands, so if possible, make the loop as
large as possible and forget 'resonance'.
Your autotuner may not be able to handle the
impedances on all bands. Autotuners generally have
a fairly narrow matching range. You can 'play' with
the length of the feed line to make the un-tunable
bands acceptible to your tuner, though.
Low horizontal loops are fairly common and they
do work well. They aren't necessarily 'short distance'
antennas at all, DX signals don't always come in at
'low' angles, you know. Give it a shot, you just might
be pleasently suprized at how well it will work.

"D.J.",
That's an odd one, but I would also think that a
gas meter being struck by lightning is also pretty
rare. Call your gas company and ask to speak with
one of their engineers about the 'grounding' issue.
If you think you may have a problem, they will be
more than happy to take a look at it, or explain it
to you. Regulations are different for different
parts of the country, but in general, gas meters and
lines are NEVER a good ground point for other systems.

Shortly after posting this I realized that the reason I measured direct current was due to my rectifier, duh. Obviously, the current is ac and it was necessary to rectify this to read it on a dc ammeter. This morning I checked my meter and it was reading nearly zero. We do not have natural gas, only electricity with geo thermal heat so it will be interesting to discover what is causing the 20ma of current.

4729. 40 m dipole?? How much of leg can I bend??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-08 18:33:11 UTC
From: StarGazer <pti@capnet.com>
Message-ID: <3D7B97E7.F55480AC@capnet.com>
Source record: 134974

One end of my resonant coax fed 40 m dipole needs to be bent
90 deg straight downward on one end.
Thats about 10 ft or 1/3 of one of the legs.

Will this affect its performance much??

4730. antenna OM ?

Hello,
What think:
Use a radiant tower (1/4) en AM on 1485Khz for a local radio with 1Kw
adapted by gamma match and connected on the ground (without insulator).
The radians of ground have a length 1/4 waves each one and are 120.
Think that this system will function as well an insulated tower ?
This method is very much used by the radio hams on 1.8Khz but for the
stations of radios the system is good?
Thank you

> [Just for kicks, could anyone run a antenna model on a "Zig-Zaged" WBFD
> using my parameters?]
>
---- In general, the radiation pattern for any 'Zig-zag'ed'
antenna
will be distorted to some extent. Probably about the same
pattern as the doublet.

> I have never used parallel feedline before. What is the potential in
> causing qrm in this Doublet installation?
> Will using parallel feedline be more susceptible to man-made noise?
> Which antenna tuner for the Doublet would you recommend for 100W?
>
---- Actually, I think the probability of parallel feed lines
being
susceptible to man-made noise is about the same as for coax,
with
coax having a slight 'edge', maybe. The potential for QRM is
equal,
coax or parallel feed lines. As far as a tuner, I would find
one
that has a wide usable range, that usually means a physically
large
tuner. I use an old Dentron 'MT-3000A', which has tuned
anything
you can reasonably (and unreasonably) expect to work as an
antenna.
But it certainly isn't the only one that works well.

> Considering the very limited height (16' from surrounding ground level, 22'
> from the full sized 1600sq/ft basement floor) above ground of any of these
> antennas, would any one be a better choice over the other? Will they all be
> cloud warmers?
>
---- Any antenna that low to the ground is going to have more high
angle
radiation than low angle radiation. Of course, the higher you
go in
frequency, the lower the radiation angle. And not all DX

'hits' your
antenna at a low radiation angle.

> Would using a pre-amp/pre-selector such as a Vectronics AT-100 be advisable
> with the WBFD to possible offset its negative gain (relative to a dipole) as
> well as possibly reducing band noise using the pre-selector?
>
---- I'm not a fan of preamplifiers. They don't change the S/N
ratio and
usually make the noise just as loud in relation to the signal
as without
they're use. I would tend to say not to bother.

With your limitations there really are no 'good' choices, just
make the
best of the 'bad' choices (as your doing). Having had some
experience with
the other antenna, I would have to 'lean' towards the W9INN
antenna. But,
I've never used one, so take that for what it's worth.
Good luck. I'd be interested in hearing how things turn out
for you...

4733. Re: G5RV or W3DZZ ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-08 18:56:05 UTC
From: IE <m9191@abc.se>
Message-ID: <9m5nnu0bnnc3jub36fnj470brf9qtu5l5d@4ax.com>
Source record: 134973

Hi,

I can just tell you from my own experience and probably other HAMs had other experiences.

I have a G5RV with 300 flatcable and a W3DZZ mounted at the same height (to low, just 8-9 meter) and with the feeding point close to each other (just one meter). The heigth of the ends has been a bit different to separate them a bit. The coax was RG213 except the last part to antenna (RG58).

The directions has been similar (N-S) even if the W3DZZ was more shaped as a soft horisontal V.

I have had different W3DZZ in about 35 years with just one or two years off. This is the first G5RV I ever have made.

The SWR for the W3DZZ is cut-and-try tuned to very low on all bands. The SWR for the G5RV is a disaster. Mostly around 3:1or higher and never below 2.5:1. An antenna tuner is a must.

I am surprised of the G5RV. On all bands it works better than the W3DZZ except for shorter distances (around 2000 miles or less). There the W3DZZ mostly is better. With better I mean better S-readings and better QSO-reports. On 80 meter I think they are very equal at longer distances.

G5RV works on all bands for me except 160 meter but I have not made the feeder cross yet.

I also have a multiband GP for 10-15-18-20-30-40 (and 80), a beam and some other wire antennas so I can use them as references as well.

The only disadvantage I have seen with the G5RV is all kind of intereferences. Beside that I don't like antennas that insist of an antenna tuner. But as a multiband antenna I am just confused why I never have tried it earlier.

Now I plan to do a halfsize G5RV as well (nice to have for portable use) and compare both of them.

So far I have not tested the G5RV with my linear and I think the real problems start if I do that. On the other hand I never used the linear on the W3DZZ but barefoot gave no interferences.

Make a test yourself. The wires is easy to play with.

Jeff,

I've jury-rigged two radio-schlock TV rotors to work az-el moving an 11 el 2 meter and 8 el 440 beam with no problem.

All I did was to use short lengths of black iron pipe and fittings to make an "L". I put the verticle pipe through one rotor, for the AZ motion and secured the other rotor to the horizontal piece as close to the bend-fitting as possible. Then ran a light aluminum tube through the AZ rotor to hold the beams. Did it look great....no!....but it lasted through 3 New Hampshire winters.

Best Regards,
Peter

Thanks Doc,

I was only thinking in terms of lightning protection. You should have seen the damage to this nice house. Lucky the family got out, but the fire was fed with gas from the broken meter I would guess. It's really strange to me at least that lighning would strike a gas meter which is about the lowest object around, almost right on the ground. Something else had to attract the lightning, pine trees maybe or the pool??

Yes, rather negatively.

> If so, what kind of angle away from the mast should I have the ladder
> line and which direction should it go in relation to the wire?

You can be parallel to the mast as long as the ladder line distance from the mast is at least a couple times the spacing between conductors. (If your line has 1" between conductors, keep it at least 2-3" away from the mast.) Try to keep the distance from each conductor to the mast about equal (meaning keep the "flat side" toward the mast).

I made something similar to what you're describing. I hung the dipole from an 8" plant hanger bracket from the hardware store, and brought the ladder line down the guy rope until it was right above the back of the shack, and let it hang straight down from there. I had an SGC SG-237 autotuner mounted to the back of the shack, with a coax run to inside. Worked quite well.

If they ask for you name etc - just say "No." If they say they need a name etc - tell them to use their own. Every RS store that I have frequented has a generic account already set up. They don't like to use it (I suspect that they are scored on percentages of people who give their address etc), but will if you refuse to play their game.

Use cash, as they will harvest your name and address off a credit card or check payment.

"Should these things (gas meters) be grounded ur are they already grounded?"

Gas meters are effectively grounded in most cases. If the burnt house had plastic water supply and plastic waste water drains, the gas supply pipe may have been the easiest path to ground for lightning on house wiring and piping.
The electric power service or other grounds need to be very good in a house with plastic pipes.

Best regards, Richard Harrison, KB5WZI

Don't bet on it. All gas residential installations these days seem to be done in plastic. Only the main trunk appears to be steel, all feeders I've seen are plastic.

hey jeff i have done this using the old alliance U100 or the U110
these work great cause the mast passes thru the rotor allowing you to mount an antenna on either side
there are issues with waterproofing the rotor cause it isnt designed to lay on its side and there are also issues with antenna balance you need to have both antennas roughly the same boom lenght and weight with out going over the weight and wind loading of the rotor thats your elevation side
then you just pick another rotor of your liking and use it for azm.
keep in mind doing it this way saves a ton on $$$$ but you have to be an octopuss cause you have a hand on each rotor control box and a hand on each radio VFO adjusting for doppler and another to key the mic
i tried this set up back in the days of AO10 and AO13 and found i didnt have enough hands

now even if you spend $600 for the rotor then you would need the interface to the computer so your tracking software can take care of the rotors for you and if your lucky it can tune the radio too then all you need to do is sit back and key the mic
good luck and happy hamming

4753. Re: Skin effect experiment with disk on antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-09 00:16:35 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D7BE863.2010207@eznec.com>
Source record: 134994

This experiment doesn't test skin effect. The problem is that the current on each surface creates a field. These fields aren't isolated from each other, so the field caused by the current in each side creates a current in the other side. Similarly, the currents in the sides couple via fields to the currents in the wires. The model of currents flowing in isolation on the two surfaces is flawed, so any conclusions drawn from the experiment are also flawed. This should actually come as a relief, because if the simplified concept of currents were correct, I believe you've also shown propagation faster than the speed of light.

To test skin effect, you have to isolate the currents' fields from each other. Of course, if skin effect didn't exist, you wouldn't be able to isolate them (and a couple of centuries of theory would be wrong, and antennas based on it wouldn't work).

I propose the following experiment. Put a battery powered RF source and small antenna into a sealed metal box. It should be completely sealed -- soldered circuit board material should suffice. Then try to detect any sign of the RF outside the box. The antenna will induce current on the inside of the box -- how much of the shield current can you detect from the outside? If skin effect weren't a fact, you'd easily detect the current.

If you don't believe that the antenna would induce current on the inside of the box, do this instead: Get a piece of copper pipe, a rigid wire, and a couple of end caps. To the center of the inside of one of the end caps, solder a 50 ohm or so resistor. To the other end of the resistor, solder the rigid wire, and extend it through the pipe. Solder on the end cap with the resistor. Now what you have looking into the open end of the pipe is an air dielectric coax line terminated at the end with the resistor. Make a small battery powered RF source (one of the little IC-sized crystal oscillator modules would do nicely), and connect it across the coax at the input end, then solder on the other pipe cap, sealing the whole thing up. I think you'll agree that there's current flowing down the center wire from the source, through the resistor, and along the copper pipe back to the source. See if you can detect this current by any means from the outside, or if you can detect any kind of voltage drop along the path of the current.

If you're well acquainted with good feedthrough and bypassing techniques, you could instrument the inside of the pipe (as well as powering the oscillator from outside). Oscillator current could be measured, or you could measure the RF current by connecting a detector diode to the resistor and running the DC out. Armed with this, you could do whatever you want to the outside of the pipe to try and disturb the current on the inside -- bury it, put ferrites along it, whatever, and

see how much success you have. But don't try this unless you really know
how to do a proper feedthrough, because any escaping RF will invalidate
the experiment.

If you do show conclusively that skin effect doesn't exist, be prepared
for fame and fortune!

I have a similar problem with antenna restrictions and very limited attic space.
I have had good success with separate inverted V dipoles on 10, 15, and 17 M with the feed points at the roof apex. Have also used the 17 M dipole for 20 M operation with the aid of a matching network at the transmitter end. Power line qrm is minimal, since the utilities are underground.

4755. Re: feeding a magnetic loop ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-09 00:26:33 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D7BEAB9.4040506@eznec.com>
Source record: 134996

A "magnetic" loop responds (when receiving) to both magnetic and electric fields, and produces (when transmitting) both magnetic and electric fields. Very close to the loop -- within a fraction of a wavelength, the ratio of electric to magnetic field is higher than for a short dipole, but beyond that, the electric field is actually more dominant than for a short dipole. (That is, the loop's electric/magnetic field ratio is higher.) The relative response (when receiving) to the electric and magnetic fields is essentially the same for any small antenna if the source is more than a wavelength or so away, and the field from all small antennas (when transmitting) has the same ratio of electric to magnetic field beyond about this distance. This ratio is determined by the medium, not the antenna, and for free space or air is about 377 ohms.

In a coaxial cable, there's a circular magnetic field between the conductors, and a radial electric field extending from the center conductor to the shield. If the cable is properly terminated, the ratio of these fields (electric to magnetic, or E/H) equals the characteristic impedance of the cable, 50 or 75 ohms for most common cables.

If the cable isn't properly terminated, the E/H ratio of the forward and reverse travelling waves is each equal to the characteristic impedance, but the fields from the two waves can add to create other ratios at various points along the cable.

It crossed my mind, Chuck. And now that I think more about it, an H-loop is probably a good idea. I simply need to be sure that the gutters and downspouts are made with vinyl instead of aluminum the builder typically uses.

I made a fairly close estimate for the circumference around the eaves and I came up with 243 ft (74M)! That is not too shabby. Looking at W4RNL's data this may be a go: http://www.cebik.com/hl.html

---

1 wl loop (70'/side, side-fed:) #12 copper 35'up over medium earth:
~Freq. TO angle Max Gain Feed Z Pattern notes
MHz degrees dBi R+/-jX
3.5 90 5.09 65 +j 4 oval thru sides
7.1 44 6.73 275 +j130 oval thru sides
10.1 35 6.86 285 -j535 lobes at corners
14.1 27 9.69 265 -j165 4 lobes at corners
18.1 21 11.65 400 +j180 6 lobes, strong=far side
21.1 18 10.61 400 -j120 many lobes, strng=far side
24.95 15 11.08 370 +j 45 many lobes, strng=far side
28.1 11 11.83 250 -j180 many lobes, strng=far side

Although his H-loop is 280ft @ 35', compared to my 243ft @ ~16', I would guess that his model would still be valid for comparison purposes. Although my loop would be slightly rectangular, according to the model it would probably work DX on 40m pretty darn well.

From W4RNL; "For all-band use... The HP loop elevation angles are close to those of a single wire doublet"

And

"let 3/4 wl be about the absolute minimum for the antenna."

This one is not a bad idea Chuck. I initially didn't consider it as viable until you suggested it and after reading W4RNL's url. What is intriguing is that I could go ahead with something else in the attic and also run this loop around the house. I'll have an opportunity to compare the two. Then again, I could mount something for 2m up there instead.

What I do need to know is what effect does the length of the balanced feedline have? In my case the minimum length I could feed this H-loop with would be about 16-20ft. I have no experience with balanced feeders so I

don't know what the significance of its length has on matching the H-loop and the possibility of causing QRM/TVI, etc.

BTW, anyone know how well a Johnson Matchbox would load this configuration? I'm considering purchasing one for this antenna. If I could find one that is in very good shape. Has anyone modified a Johnson for use on 160m? Would I be able to match my H-loop with it on 160m?

Thanks,
Stan

'Doc wrote:
> On 40m it will be the second
> harmonic for the antenna and that is almost always
> not 'good'.

There's absolutely nothing wrong with the second harmonic of
a dipole or loop. My 130ft dipole fed with 450 ohm ladder-line
works efficiently on 40m with gain over a 66ft dipole. This
Old Wives' Tale originated because one shouldn't use coax on
a one-wavelength dipole. Ladder-line is a completely different
story. 450 ohm ladder-line gives the same SWR for a 50 ohm
dipole and a 4050 ohm dipole.

The feedpoint impedance for a 2WL loop is a very reasonable
value for ladder-line.

An SWR of 3:1 is not a disaster. The G5RV is a good antenna for 75m,
40m, 20m, & 12m. It is common knowledge that a G5RV requires an
antenna tuner.

This area was serviced with gas quite recently and all piping was
plastic, including fairly large diameter trunks laid along the highway.

My meter is fed by plastic underground pipe and feeds gas into the
building via a plastic pipe.

I note that there is an insulated wire wrapped around, but not connected
to, the pipe at each meter. I surmise that this is used to inject a
signal to locate the non-conducing pipes. Older installations in this
part of the country do not have this wire, and I assume that is because
the pipes are metallic.

> shields for electrical circuits working at radio frequencies."

I have trained with the same books as you so I find it equally troubling
when I run an experiment that contradicts the book. But the experiment gave
the results reported and the results clearly indicate that skin effect does
not separate the surfaces.

So how about recognizing that multiple currents yield a single field that
is sum of the original fields? If two currents are 180 degrees apart and
are equal, the fields will cancel completely.

>
> Coax and waveguide don`t allow r-f in or out through their walls. They
> are impenetrable. Disks aren`t needed anywhere to prove this. Why can`t
> you normally pick up cable TV signals without connections to the cable?
> Shielding!

Certainly this disk experiment indicates that the fields can penetrate the
walls. However if the currents were equal and opposite, they could not be
detected. Normally the TV company will keep the currents in the cables
equal and opposite but when they don't, the cables will radiate.

>
> Best regards, Richard Harrison, KB5WZI
>

What the books should add to make the cancellation concept complete is that
the fields will not cancel if the induced current can not flow in an
unrestricted manner. Thus for example, if we want to add additional

shielding to a coaxial cable to correct for the 95% shielding generally provided by manufacturers to make it more like 100%, we can not do so by placing short lengths of additional braid layer over the cable so that skin effect will shield the cable. No, the additional braid must be continuous and connected at the ends.
(Yes, you can use short lengths if they are tuned to the frequency inside the cable).

Shielding equipment is notoriously difficult. Part of this is due to the incorrect idea that skin effect does the shielding so that RF fields can be contained just like light can be shielded and held inside a box. The biggest cause of shielding difficulty is that once a circuit is unbalanced, it is very difficult to bring it back into balance.

The disk antenna experiment should be repeated by others. It clearly challenges the theory that skin effect has shielding properties.

> RS will be much better off without your trade thanks!!!
> Please take you business elsewhere !!
> oh you don't have anywhere else?, too bad!!
> Bye!!!
> I'm one of the so called Morons that work for RS!!
> Ever thought that it might be RS that gets the Staff to try to sell Cell Phones
> and Sat Dishes? thats where RS makes most profits!
> Like all stock market companies they want the best profits for the stock
> holders!!
> Cell Phones and Sat Dishes pay the best commision to the staff too, Jerk !!!!

Wonderful attitude, friend. I recently had an encounter of a similar nature with the RS store near my office. I came in during lunch to try to find a mobile radio bracket to use with my FT-817 radio. The gentleman behind the counter was very polite (you could take lessons from him), but told me he didn't have any in stock and neither of us could locate them in the catalog. I asked why it wasn't available, and was told that they're rearranging their inventory "to push the good stuff." (He explained that the "good stuff" was exactly what you mentioned -- satellite dishes and cell phones, which provide better margins.)

Now, I can understand a business decision like that. And I was certainly not angry at the salesperson who provided the information. I =am= disappointed that Radio Shack -- up to now my first point of contact when looking for electronic items, ever since I was old enough to handle a soldering iron! -- has chosen to make that decision. The problem is, if you don't provide the other services and products that many of us have come to depend on from Radio Shack, we're not likely to come to you when the time comes for us to consider a cell phone or satellite dish purchase. And attitudes like the one you just demonstrated serve more and more to push potential customers away.

And did you know that your message will live on for many years in the Google archives? Anyone searching the newsgroup archives there for anything to do with Radio Shack will see your message....

Point of record: at one time I worked for Radio Shack, in one of the stores in San Bernardino, CA. I was in the Air Force at the time, and took on a part-time job with RS for some extra spending money.

So yes, I have some issues -- and experience -- with Radio Shack management. And I only wish I knew the store where you work -- no doubt your store manager would love to know the kind of image you're

portraying out here on the 'Net as a so-called RS representative.

You may want to learn some people skills, or at least do some growing up.

(Don't bother with a reply -- you already made my kill file.)

Dick Carroll wrote:
"Don`t bet on it (Gas meters are effectively grounded in most cases)."

Considering the average age of gas installations, the statement is true.

Considering the particular incident of lightning setting fire to a gas meter, it`s likely that the meter was in the electrical path of the lightning. One terminal for the discharge was surely the earth.

Pipedope on meter risers only provides a low breakdown voltage dielectric. It`s a flashpoint.

Gas water heaters unite water and gas systens. Gas ranges and heating systems unite electrical and gas systems.

Lightning on one system is likely to spread through the others.

Best regards, Richard Harrison, KB5WZI

I guess my question is why do people spend 100's of thousands of dollars for a house that has so many restrictions. Talk about the "land of the free". If you want to preserve your freedoms then don't buy land with restrictions....

If I pay that kind of money I would make sure I can do with it what I want. As per the FCC deed restrictions can not be applied to TV antennas. Put up a tall TV antenna, run a coax up the TV pole and connect the coax to the two guy wire (correctly insulated of course) and presto you have an inverted Vee.

Probably will improve the over all performance in that your pattern will be more omni directional rather than the classic figure 8. You lose gain in two directions but have a better chance of working stations off the ends of the antenna. The half square windom from Antennas and More http://www.antennasmore.com/windomhq.htm uses a 66 foot flat top and two 33 foot tails, the Carolina windoms from Radioworks use tails also. I use a center fed inverted L with one half horizontal and one half vertical. Try it and see what happens.

If what you say about skin effect were true, then how do you account
for the fact that a fully
shielded cable like that used for cable tv or any other solid shield
cable does not radiate. But at
the same time a cable that has only 95% shielding will radiate. ? Both
cables can be installed in
the same circuit with the same "balance" as you refer to. Shouldn't
they both radiate if skin
effect does not exist.

Why do you think that large coax cable like 7/8 hard line has a copper
tube for the center
conductor and not solid core wire?
Answer: A solid core would be a waste of copper as rf does not
penetrate very deep into the
conductor. Skin effect.

> all around compromise?)

I'd go for #2 myself for all band use. I have a 40 meter dipole in the attic fed with 300 ohm line with a tuner. It works pretty well I guess for 40-10 use. Lower for receive only. I don't really find ladder line much worse than coax as long as the antenna is center fed. I use a Z dipole on 160m. The pattern is little changed from a normal dipole. If I remember right , like say 1.8 dbi gain compared to 2.1 dbi for a regular dipole. If I were to work only one band, I use coax to the Z dipole. I didn't want to be stuck to one band though. I don't know what a W9INN dipole is. If the overall lengths are about the same, I'd just use the regular doublet made from cheaply available wire. I can see no point in using a "special" dipole, loaded or whatever, if you are going to be using ladder line and a tuner. You could add loading coils to improve low bands, if it's short, but you can make those if needed. MK

What I would do in a case like that is have a gap and a jumper at the far side of the loop from the feed. That way you can go out and convert it from a 80 m loop to a 160m dipole. That should give better 160m performance than trying to run the 80m loop on that band with a tuner. MK

4773. Tiltable baseplate

Message-ID: <3d7c0c2b.7670892@national-news.stargate.net>
Source record: 135015

Hi all!

I'm searching for the manufacturer who made a hinged baseplate, 2 pieces, with 4 spikes on the bottom, roughly 14 to 18 inches long, to push into the earth for the support, and a 4 to 6 inch piece of 1-1/2" pipe on top of the tiltable plate to mount a mast or a vertical. I've been looking through the recent QST's and checking the websites, but to no avail. I've seen it, as well as a couple buddies of mine, they're in the search too. If anybody happens to come across this item, I'd appreciate you letting me know.

Thanks!!

Jeff Y.

Pretty well what I saw except for the main supply trunk that brings the gas
from afar was welded steel, presumably because of the much higher pressures
involved. The local supply feeders were plastic also.
Looks like all lines that operate at low enough pressure are going to be plastic
from now on.
I'm rather sure you're right about the wire, it's for locating the line, not
for a ground.

Dick

> Rich - W2YQ

Yes, but this is sort of skewed as most hamsticks are poorly designed
as sold, and use too short of stingers. I've got a appx 10 ft or so
stick for 40m that works very well. About as good as my bugcatcher
style antenna. But my 40m "stick" is really a 6 ft 20m hamstick with a
long 4 ft stinger on it. Works way better than your run of the mill
40m hamstick with too many windings and too short a whip. I've never
had a problem working anyone with that antenna. I get just as good of
reports as the guys running bugcatchers for the most part. I think I
actually beat a few of them that use shorter bugcatchers, and smaller
cars or trucks. A large bugcatcher is hard to beat, but you can make a
"stick" type antenna work very well if you set it up right. "long
whip, and most of the windings at the top of the stick for better
current distribution" I have many people that can't believe it when I
tell them what I'm running. Happens almost every time. Happened the
last time I used it a week ago. I'm LOUD with only a 100w radio. And I
do also have a large coil antenna to compare it with. There is not
that much difference between them on 40m. But I agree, the "usual"
storebought 40m hamstick leaves a lot to be desired. Mine will eat
one of those things for lunch. I use only the large coil antenna on
80m. To make a decent 80m hamstick would make it too tall to be
practical. I could make one 10 ft tall work "ok", but not as good as
the bigger coil. It's way more critical on 80m than 40. MK

Draw up some plans that fit your tower, then find a good welder to build it.
Thats what I did with a person I knew to make his tower a tilt over.

I have found that LPDAs using a boom/transmission-line profit from a
choke where the transmission line bridges the boom to mast transition.
Just wind the same piece of coax that is attached to the front of the
booms into a coil. W7EL has discussed the preferred coil.
Without the choke, the pattern is often distorted by feedline
radiation.

Roger, W7WKB wrote:
"Shielding equipment is notoriously difficult. Part of this is due to the incorrect idea that skin effect does the shielding so that RF fields can be contained just like light can be shielded and held inside a box."

A box doesn`t have to be electrically conductive to contain light.

The books are correct. It is skin effect which makes a copper box inpenetrable to r-f.

Evidence is that 2.6 inches of copper thickness is required to prevent 63.2% of the current density at one surface from appearing at the other surface when the frequency is 1 Hz.

Only one 1000th of that thickness is required for the same attenuation at 1 MHz. The skin depth is related to the reciprocal of the square root of the frequency. The square root of a million is a thousand.

A practical example of non-conductance of r-f through a shield exists in a laboratory signal generator. You have a meter to show a healthy signal within the box. Crank in maximum attenuation to the output. Signal is undectectable outside the box using a high gain receiver either connected or disconnected to the generator output.

Best regards, Richard Harrison, KB5WZI

I'm not so sure the FCC regs are that cut and dry. I think you have to show
inability to receive a clear reception. But I could be wrong. Heck, I
can't even figure out a dipole and I should make heads or tails out of FCC
regs? Hi

Are local city ordinances that allow for amateur towers superseded by deed
restrictions?

(i) Exempt Facilities.

1. Amateur radio towers installed, erected, maintained and/or operated in
any residential zoning district, by a federally-licensed amateur radio
operator, complying with the provisions contained in Chapter 17 of these
ordinances, so long as all the following conditions are met:

a. The antenna use involved is accessory to the primary use of the property
which is not a telecommunication facility;
b. In a residential zone, no more than one support structure for licensed
amateur radio operator is allowed on the parcel;
c. Sufficient anti-climbing measures have been incorporated into the
facility, as needed, to reduce potential for trespass and injury.

I had read in the archive somewhere about placing chicken wire near the ends of the dipole as some kind of capacitive hat?
His situation was exactly as mine. On the inside of the far ends of the attic walls he attached chicken wire using cardboard between the wall and the chicken wire. He didn't describe the dimensions but said to make each hat equal in size. It effectively increases the length of the doublet. I wonder how the chicken wire would effect the ends of a "Z"-doublet?
Another good experiment.

> I'm interested in creating an az/el antenna system with el-cheapo
> rotors (as opposed to dropping $600 for a Yaesu GX-5000).

I've done az/el with a pair of old Alliance U-110 rotors; the ones where the mast goes completely through the rotor.

The main trick is to make up a plate to allow mounting the elevation rotor in the horizontal direction, which is what I did. I've also known people to use two short pieces of pipe with an elbow making an inverted-L shape. (You need to pin or weld the pipes to the elbow.)

One caveat: You *must* take steps to rainproof the elevation rotor. (You don't have to make it waterproof, though.) I used a piece of aluminum flashing in a big "C" shape and mounted it to the plate, and bent the sides in to protect the sides. Others have taken a plastic garbage pail, punched holes in it for the crossboom, and just used that. Ugly as hell, but it works.

U-100s and U-110s used to be plentiful at hamfests, but I haven't seen many recently. (Alliance is out of the rotor business.) Norm's Rotor Service (http://rotorservice.com/) bought out Alliance's inventory, and has new ones for sale. Not cheap, but they *are* new and carry a 1 year warranty.

Thanks on the replies. I thought MFJ had one andt he price of $100 is
a bit steep for an item like that and I'm still trying to confirm it.

As for the plans and getting a welder, I've already decided that if
this can't be found and at a reasonable price, this would be the road
to go.

Thank you for your comment. Yes, I know the fact but for a person looking for "self running antennas" it looks awful..... but it works fine.

I have one question around this. How good are the automatic antenna tuners in times of "mean time between failure"? I have a TS870 and it has to work a lot when I switch between DZZ and G5RV. To hear it work remainds me of all that can go wrong in mechanical things. Just a thought but does anyone know?

rsparks wrote:
> But the experiment gave the results reported and the results clearly
>indicate that skin effect does not separate the surfaces.

No, they didn't. What you reported here on the newsgroup was misleading compared with the more complete report on the web page.

In the newsgroup, you said: "If you don't have time or the ability to look at the web page, I can tell you that the metal disk did not lower the resonant frequency of the antenna."

But the web page says: "The addition of the disk RAISED the resonant frequency of the antenna about 0.5 Mhz."

This is completely to be expected. The disks were 12in diameter, placed 5in each side of the feedpoint, so they were acting as the plates of a capacitor. Your definition of "resonance" is where the feedpoint reactance crosses through zero, and adding a capacitor almost directly across the feedpoint will indeed raise the frequency.

In other words, what you wanted to look for was swamped by another large effect that you chose to ignore because it didn't fit your theory. That's bad science.

260 feet should work well mine is 525 feet , if you want to use your's on
160 it should be as big a possilbe.. the 260 feet will work very well for dx
on 40 meters and above. on 20 and above you may want another antenna like a
vertical or dipole to fill in the pattern nulls ..
I worked qrp dx cc with mine mostly on 40 and 30 meters. at the 4 watt
level. mine is at an average hight of 30-35 ft.

Give yours a try.. and give it some time. at first you may think it's not
that great but over time it will prove it's self.

Well, I use a sling shot to set up my 6m dipole and also my "roll up"
2m jpole when backpacking. Alternatively I also use it to set up my
bear line to keep my food safe.

I've hiked in many placed where a sling shot is not permitted, but
there is little mistaking mine for a weapon.

Its a simple sling shot with a cheapo $10 wallymart fishing reel
bolted to the bottom. Reel is loaded with 12lbs bright yellow fishing
line and has a massive lead sinker at the end of the line.

I've been accosted by Rangers and Wardens in the Adirondacks and in
federal parks here in Canada when they saw my slingshot and once I had
demonstrated how I used it to set up a bear line on a nice high branch
they were amazed and thought it was the best thing since sliced bread.
Most Rangers may not care much about our amateur antennas, but for
things like lines for keeping food safe from wildlife it's another
story :)

I guess a little demonstration can go a long way in changing their
perspective.

>activities, what can I install : the G5RV or the W3DZZ ?

In my experience, the W3DZZ-type antenna is slightly better for your
application than the G5RV. By "W3DZZ-type", I'm referring to a dipole of about
110 feet with two identical traps resonant on 40 meters. Dipoles with more than
two traps are another story.
>
>Hints : According the theory, the second solution seems better : one
>type of feedline, easy to use as inverted V in necessary, traps allow
>to be resonant on L/2 on various bands and even 3/2L on 20m, 5/2 on
>15m, etc.

The W3DZZ design has at least three basic variables:

- Length of the inner dipole sections
- Length of the outer dipole sections
- L to C ratio of the traps.

By careful adjustment, the W3DZZ antenna can be tuned to resonance on at least
three bands (typically 80/40/20) and the 15/10 meter bands will be pretty
close.

>As traps quality if very important in this model of dipole, do you
>know a good manufacturers of W3DZZ, famous of the quality of its
>antennas ?
>
The main concern of trap quality is low loss, which equals high Q. Best way to
get that is to build the traps yourself, using air-wound coils and
transmitting-type capacitors.

The main downside of the W3DZZ design is that unless you are very lucky, it will need adjustment. You need at least a dip meter and SWR bridge for adjustment.

Unless the feed line is very short and/or you are only considering bands below 10 MHz, please consider using lower-loss coax than RG-58 type. RG-8X type costs about the same money, is only slightly bigger and has less loss.

The audio people will buy about anything that is gold plated and sells for a high price. Saw some power cords similar to those in an audio magazine at about $ 100 for a 6 to 8 foot cord.The people jsut don't think about the 20 to 100 feet of wire from the plug to the fuse box or back to the power pole.

If they only know that you could cut the cord to 1/2 wavelength it would work beter :-). I might have to look it up but I only calculate about 1400 miles not counting the velocity factor :-)

Surely there is a major trade-off here between high Q traps with narrow bandwidth and low Q traps with wider bandwidth? If, as you suggest, high Q components are used, the bandwidth will be insufficient to cover a whole band, even on our restricted 40 in the U.K. I would suggest that going for the highest possible Q is not the main concern, but rather to find the best compromise between bandwidth and efficiency.

I think the high Q solution is to have an untuned antenna a la G5RV and use variable high Q components in the matching unit (and low loss open wire feeder).

> from the experiment are also flawed. This should actually come as a
> relief, because if the simplified concept of currents were correct, I
> believe you've also shown propagation faster than the speed of light.

Richard Harrison in an earlier post conveniently provided a quote:

"The 19th edition of the ARRL Antenna Book says on page 23-2:
"In good conductors the speed (of r-f wave travel) is so low that the
opposing fields set up by the wave front occupy the same space as the
wave itself, and thus cancel it out. This is the reason for "skin
effect" in conductors at high frequencies, making metal enclosures good
shields for electrical circuits working at radio frequencies.""

The disk in the experiment is made of solid 0.062 inch thick copper plate
with no holes in it. This is about 10 times thicker that the diameter of
the
wires which make the shield of RG-58 coaxial cable.

It seems to me that the disk meets the definition presented in the Antenna
Book much better than does coaxial cable, so we should see the shielding
provided by skin effect in the disk if it were really present in coaxial
cable.

Yes, if the current went around the disk (not through it) and the resonant
frequency
stayed the same, then the travel around the disk would have to be
instantaneous.
I don't think that is happening. I think the current is going through the
disk despite
the words from the Antenna Handbook that say it can not due to skin effect.

>

> how to do a proper feedthrough, because any escaping RF will invalidate
> the experiment.

I am surprised that you do not give credit to the effect of the opposing
currents
that would be created in the surrounding metal. The fields of the induced
currents would be opposite the center fields so would cancel the field from
the
center, just like they do when we model antennas. There is no need to call
upon skin effect as a shielding mechanism when opposing fields can do the
same job.

I notice that you did not specify a frequency for the test, nor a thickness
for
the shield metal. Of course there is no need to because the results will be
the same for all frequency and metal thickness choices.

>
> If you do show conclusively that skin effect doesn't exist, be prepared
> for fame and fortune!

Skin effect is real so far as currents parallel to the surface are
concerned.
The claim that a shield is created by skin effect is under attack by the
results
of this experiment.

Antennas are scalable. A full-size G5RV has a design frequency
on 20m and works well on 80m, 40m, 20m, & 12m. A half-size G5RV
has a design frequency on 10m and works well on 40m, 20m, 10m,
& 6m. Anyone can verify such with the free demo version of EZNEC
available at http://www.eznec.com

Yes it should, but your set-up was far too error-prone to reveal it.
Further, even casual observation of the photos reveals you had a world
of problems with almost everything under the sun (including yourself)
between those two capacitor plates you added.

>
>Yes, if the current went around the disk (not through it) and the resonant

And yet your own results are unaccountable to your theory. This again
was the red flag of the hodge-podge of assorted non-antenna extra
physical features filling the space between the plates that skewed the
data.

>I notice that you did not specify a frequency for the test, nor a thickness
>for
>the shield metal. Of course there is no need to because the results will be

This, of course is speculation, and as it is required to support your
theory, it demands proof (more tests - better ones too) not just
wishing and hopes.

Hi Roger,

Well, in fact it has easily survived the attack and remains intact and proves fame is nimble in avoiding usurpers. It has already gotten you to allow it exists for one example (although you do not appear to have that down either), cabling, where you now argue that there is a special case, disks, where it does not. As physics is not a pliable argument that stretches to cover poor data, the flaws in your position are irreconcilable.

One test does not constitute science. If your theory is valid, it is valid everywhere, not just in isolated instances. If it is valid everywhere, it is demonstrable everywhere. You lack showing the everywhere, much less the anywhere. As Ian pointed out (and you have yet to respond to), the errors are glaring. The only response to this is to make more tests moving these plates out and away from the center.

This should conform to the logic you have offered. If the plates did not lengthen the electrical length of the dipole at one position, they should not for any number of positions along the length of the dipole. You clearly lack that data to support your theory - and you will be hard pressed to find it. This simple confirmation (either way) is obviously within your ability to perform - judging by those same photos.

Like I said earlier, looks like you need to do something different. Barring that confirmatory data, what you've offered obviously doesn't do the job.

Paul,

According to the Aug QST article, the MFJ looks reasonable. If you care about the top end of 10m, you might want to consider the Nye-Viking. If you are getting TVI on ch-2, the Bencher YA-1 is good, has slightly more loss at 29.7 MHz.than the Viking, but much better at 29.7 then some of the others. I have the Bencher. Like the other response suggests, read the article. Look for SWR, loss, and and Channel-2 response.

CAM, W5DXP wrote:
"A full-size G5RV has a design frequency on 20m and works well on 80m, 40m, & 12m."

True. The G5RV according to Fig 8 on page 7-5 of the ARRL Antenna Book (19th edition) is a 102-ft dipole. As such, its first resonance, as a 1/2-wave, is at 4.82 MHz.

Patterns for a 100-ft dipole are given in the same book on page 2-12. Fig 13 is the pattern at 4.8 MHz (first resonance). This would be applicable at 9.6 MHz for a 50-ft dipole.

Likewise, Fig 14 would apply at 19.1 MHz for a 50-ft dipole.

Patterns for a full-size or half-size G5RV would be practically the same as similar dipoles, similarly placed, which were only a foot or two shorter.

A 1/2-sized G5RV is less directional on the lower frequencies than a full-sized G5RV. But, on the higher frequencies, it has less pattern splitting.

Best regards, Richard Harrison, KB5WZI

The best thing to say is that I want to pay cash & I don't want my name on ANY mailing lists, if they continue to badger you I would leave the items on the counter & leave the store. Don't forget to take a manager's card & complain to them about it, they will probably give you a song & dance but the bottom line is that you are NOT required to give N&A.

If you've recently purchased and received split ferrite cores with plastic snap-on case for cables of approximately 3/8" (or 3.9 - 4.0 mm), please let me know where you got them. Please don't tell me to do a Google search and that there are lots of places selling them. What I've found so far is that there's lots of places selling 1/4" cores and advertising them as 3/8" cores. If you know for certain of a source, I'd be eternally grateful. Thanks in advance.

The system bandwidth is determined by the loaded Q, which is a function of the L/C ratio in the traps.

The losses - which were what N2EY was talking about - are determined by the ratio of the loaded Q to the individual (unloaded) Qs of the components. In other words, N2EY was simply advocating low-loss inductors and capacitors.

I'm guessing he attached a jumper to the "chicken hat" at each end.
The effect would be the same as if using a straight dipole. I would
prefer capacitive loading over inductive if I had to choose. But the
hats could just be spokes of wire. I'm not sure if I would want to use
chicken wire. I'm sure it will work though. MK

Yep, it's sad. It used to be that you could go into Rat Shack and
at least get some of the "basics" -- LEDs, resistors, caps, some
common ICs (555 timers, 78-series, etc.), connectors, etc. Their
prices were never great on that stuff, but there is always a Radio
Shack closeby, and they have good hours. But now most of the
Radio Shacks in Toronto have eliminated their "electronics
hobbyist" stuff and is instead concentrating on cel phones,
satellite service, 2nd-rate toys, and 3rd-rate computers.

And to buy even basic parts, I have to drive out to the boonies to
go to the electronics hobbyist stores.

Definitions and interpretations of Antenna Book wording aside, this
response doesn't address the obvious problem of coupled fields, which is

the fundamental flaw of the experiement.

> the
> center, just like they do when we model antennas.

In a coaxial cable, the fields cancel at any point from within the
shield to outward. This is because of skin effect: the field from the
inner conductor penetrates the field, and no field from the outer
conductor penetrates the shield. (By "none", I mean no significant
amount for a good conductor many skin depths thick. It would be
precisely zero only for a perfect conductor.) But if skin effect didn't
work, you would be able to detect the current on the outside conductor
by using a sensing device that's smaller than the pipe and putting it
close to the pipe. This is because the field from the shield comes from
current distributed around the shield -- it's the total of this field
that equals the field from the center conductor. Something like a core
that surrounds the entire pipe wouldn't detect a field, since the whole
current is going through the pipe. However, half a ferrite toroid with
several turns of wire placed against the pipe would detect a net field
or current. This effect will get more and more pronounced as the
distance from the center conductor to the shield gets greater. If your
theory were correct, you would be able to measure significant currents
on the outside wall of a shielded room (with a source inside), and a
significant net field close to the outside wall. You would also be able
to detect a voltage drop across the outside of the cable if your theory
were correct.

There is no need to call
> upon skin effect as a shielding mechanism when opposing fields can do the
> same job.
>
> I notice that you did not specify a frequency for the test, nor a thickness
> for
> the shield metal. Of course there is no need to because the results will be
> the same for all frequency and metal thickness choices.

Sorry, I thought this would be obvious. The frequency and thickness
should be such that the shield is at least several skin depths thick.
You can find the formula for skin depth in any electromagnetics text, or
in previous postings I've made on this newsgroup. If you want to be able
to measure the voltage drop along the outside of the shield that your
theory requires, you'll need to do the test at a reasonably high
frequency unless you want to build a really long cable.

>>If you do show conclusively that skin effect doesn't exist, be prepared
>>for fame and fortune!
>
>
> Skin effect is real so far as currents parallel to the surface are
> concerned.
> The claim that a shield is created by skin effect is under attack by the
> results
> of this experiment.

So far the attack doesn't seem very threatening. A valid experiment will
have to confine or account for coupled fields at the very least.

Good science is the goal.

I was surprised when the disk raised the resonant frequency. I fully expected them to lower the frequency but not by much. If skin effect were a shield, the lowering of resonant frequency should be a large number.

The capacity added by the disk is in parallel and is not much. I entered the calculated amount into Eznec and the resonant frequency was hardly affected. I did not expect the added capacity to space to have much effect as it is also very small.

Frankly, I can not explain the large capacity effect. I speculate that it may be due to the slower rate of charge velocity through the plate compared to

the velocity on the surface of the wire. If this were correct, it would be result in charge accumulation at the disk similar to the way cars bunch up when encountering a restriction in the road.

I am hoping that others will duplicate this experiment to verify my results. I ran it three times in three different locations. The results were not identical
each time, but were consistent in that the resonant frequency was never lowered like you would expect if skin effect were a shield.

I was further surprised at the broad resonant curve. Further experimenting could be done to see if an antenna could be broadbanded with a large wire capacity structure placed near the feed point like in this experiment. The use of a large metal plate like I used would be impractical for a large antenna due to the weight.

Good science is the goal.

I agree with all but lets face it.It does no good to complain...RS will survive
and survive well by catering to the eletronic appliance Toys R Us crowd.
Just have to be like an old buzzard like me and stockpile junk for
parts....Just be thankful you arent dealing with tubes the size of 1/2 gallon
milk jugs and transformers that weigh 100 lbs plus.......If I brought a 4-1000
tube into a RS the first thing the guy would say is "we dont carry light bulbs"

4825. Question for AM antenna.....

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-09 21:20:03 UTC
From: Peach <peacZZAAh@pulsLLPP124enet.com>
Message-ID: <3d7d1083_3@athena.netset.com>
Source record: 134966

Hello All,

If I am posting this question in the wrong group, please direct me to another.

I live about 30 miles South from an AM station I really enjoy (1320 AM) I am somewhat in a valley and recently a local station has upped their wattage or changed their coverage as to make a bad hum/noise on my GE Supertuner.

I have limited room for an antenna, any comments?

I will run coax to a "car Antenna" or whatever to shield that other station from interfering.

Thanks,

Joe

4826. GPS Horizontal Loop Antenna Design???

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-09 21:30:12 UTC
From: Jim Weir <jim@rst-engr.com>
Message-ID: <qh4qnu0c9i39e02c9dm0fatsd23bqe6bu8@4ax.com>
Source record: 134967

I'm diddling around (pardon me, I'm heuristically engineering) a whole potful of GPS antennas -- patch, spike, and the like.

What I'd like to try is a horizontal loop above an infinite ground plane but don't really have a good place to start. Can anybody point me to a good starting practical reference to "large" loops (i.e. quarter wave to full wave) at an arbitrary height above a ground plane?

Thanks,

Jim

Roger, W7WKB wrote:
"Good science is the goal."

Terman explains skin effect by saying a round wire has magnetic flux in concentric circles caused by current through the wire. Some of these concentric circles are within the wire. Therefore, the deeper within the wire you sample, the more total flux circles there are within and without the wire. This means the closer to the center of the wire you get, the more inductance you encounter. The wire could be square or have any cross-section and the result would be the same.

If a conductor has increasing inductance at greater depth, it also has greater opposition to a-c.

Terman writes:
"When skin effect is present, the current is always redistributed by the conductor in such a way as to make most of the current flow where it is encircled by the smallest number of flux lines (page 22, 1955 edition)."

Best regards, Richard Harrison, KB5WZI

> buzzard like me that thought it was bad when the Lafayette and Allied
stores
> went down.....IC's..Led's what are those? LOL

When I was young there was a Lafayette store in downtown Detroit. I could get on the Tunnel Bus (I live across the river in Windsor) and easily go there. I bought a Signal Tracer/Generator kit from them once. Lafayette and Allied catalogues were a great source of info. I especially liked the Lafayette catalogues.....

> > And to buy even basic parts, I have to drive out to the boonies to
> > go to the electronics hobbyist stores.

Be glad in Toronto you have these - these type of stores have never survived here in Windsor.

It sounds like the local station may be overloading your radio and more
antenna may be worse. You could try an indoor loop antenna. It has two
advantages...one, you can null the offending station by rotating it, and
secondly you can peak the tuning for the desired station at the expense
of the offending station if it is several 'channels' away.
This page gives plenty of details.

Bill,

I thank you!

I like nostalgic music from the late 40's to about 1965.....

Anyone know of a good station near Pittsburgh, PA that plays this kind of music (don't get me wrong, I listen to Pop, Jazz, Country....well almost everything, yes Polkas too...LOL)?...I listen to WJAS..1320, but lately they have got a little away from those classics...(Nat King Cole, Frank Sinatra, Dean Martin.....The wonderful Bobby Darin.....& soooo many more!

Thanks a bunch,

Joe

Hi,

What's the best solution for a mobile (car) antenna for the stated freq. range?

I was thinking of a widerange antenna with a magnetic foot, has anyone got some experience with such a device, and what are your findings?

regards Jeroen

I think if you were to try to span the stated 7 octaves, you would have a "Jack of all trades and master of none"

The tradeoffs you'd have to make would render the antenna borderline unusable on any specific band.

Of course, I've been wrong before...

HAARP has a very limited transmit schedule.
If you want to pin down any effects from HAARP,
you will have to figure out if they were on at the time.
(Last I heard, it was only a couple of weeks a year)

If you read the environmental impact statement, HAARP
is powered by diesel generators, and the operations of the
facility are limited by the total number of particulates dumped
into the air by the generators.

So much for aliens, weather control, and other black bag theories -
these guys had their butts kick by the EPA.

>--
>73 from Ian G3SEK

Thanks, Ian - you said it much clearer than I could!

I went back to the original 1955 article by W3DZZ himself. He was able to get a
2:1 SWR bandwidth of over 200 kHz using traps of approxiamtely 62 pf/8.2 uH
and fairly low loss construction. If it worked for him, it can work for you.

Also consider the "half size" W3DZZ for work on 40, 20 and 10 meters. This
antenna uses 20 meter traps consisting of a 27 pF capacitor and 4.7 uH
inductor. If a ceramic "egg" insulator is used for the trap strain insulator
and a 25 pF transmitting cap, the combination will have 27 pF.

--

Almost all simple multiband amateur HF antennas are a compromise of some sort.
Practically all of them need a tuner of some kind to work over the entire 80
and possibly the Region 2 40 meter bands.

In some circles trap antennas have gooten a bad name. See how often an antenna manufacturer will brag that their design has "no lossy traps" or some such. Yet well constructed traps can have insignificant losses, and do an excellent job.

Where traps can be a problem is when many of them are used. It is possible to build a multiband dipole that has traps for every band except the lowest, and get a nice low SWR on each band. Such an antenna will also be quite a bit smaller than a fullsize dipole for the lowest band. But the losses of all those traps can amount to a surprising figure!

You need to experiment. My guess is that if you are using a balun, go 5 feet on each end, instead of 10 all on one side. If you are not using a balun, put the 10 feet on the side that connects to the shield of the coax. You may need to trim the length.

This scales to any frequency. A 2-wl perimeter loop is nearly omnidirectional and when mounted less than 1/2-wl over a reflecting plane, radiates mostly straight up. Cebik gives the drivepoint impedances for various horizontal loops.

Shouldn't that be 3:.333 or 9:1 ?

It might not work quite so well for me and Andy in Europe, since our bands are only 3.5-3.8MHz and 7.0-7.1MHz. For optimum performance, the trap resonance needs to be moved down to 7.05MHz, and the L/C ratio changed, together with the two wire lengths. Apart from that, our trap dipoles are exactly the same as yours :-)

Nope, 9:1. The inductance or impedance is approximately proportional to
the square of the number of turns.

Hi Floyd,

The first thing you ought to do is decide whether or not you need ferrite
cores and for exactly what purpose.

Have you already been conned by the old-wives, the so-called Gurus, the
periodicals and the handbooks ?

The last things you should concern yourself with are the core dimensions and
material permeability.

Good luck with your search.

Reg.

There's an obligatory resistance associated with every Q.

It is usual to define Q as Omega*L/R.

In the present context, what is R.

> or check payment.

RS employees have a quota for names and addresses captured. At one of my favorite RS stores, there was a sales person on the floor who really 'got it.' Left me alone to buy my stuff, and after a quick brush with a steady stare, and a malevolent pause followed by a quiet 'no', never asked for my name and number again. She was terminated. Her Store Mangler told me that she failed to meet some required numbers. I ran into her at a real electronics store in the area a few months later and she told me she was let go for two reasons. One was not capturing her quota of names and addresses. The other was not aggressively pushing cell phones. This despite the fact that she had been the highest grossing sales person on the floor, commission only and making a rather substantial income.

The problem with RS, however is not the clerks on the sales floor. Or, in most cases, the Store Mangler. The problem with RS, like most businesses, is in the corner office. It's there that the culture is formed that's passed down through the corporation. It's there that the hiring policies are formed, and the requirements of performance established.

I rarely go into an RS store anymore. Better stuff is available elsewhere, with much less intrusion on the sales floor. The mangler at my local RS, who wised up pretty fast the first time I walked in there still says hello when I see him out in the community. But he doesn't ask why I haven't been in the store lately. He fully understands why...and although he doesn't dare say it out loud in public, privately admits he agrees with my decisions not to return.

RS is, for most people there, a job. There are few who consider it a career anymore. And of those, none that I've met who are into electronics.

I had a maddeningly hysterical encounter at one of the stores in Rockford a couple of years ago with a sales goof who had never heard of a shortwave radio. After bringing out several scanners, with escalating frustration because I was looking for something with HF coverage and he didn't understand that there was a difference, the mangler of the store came out. I recognized him as the owner of a hobbycraft store in South Holland I'd done spots for a few years earlier. He quickly dismissed the sales goof, and brought out a number of SW sets himself. We had a nice chat about the job, his future with the company, and how he went from owning Scale Models, to mangling a RS in Rockford.

His answer was pretty simple...RS is a sales company. He's a salesman. It was a perfect fit. I asked him if he had any background in electronics...he said "no...that's what I have YOU for."

Mike has since moved on. He was frustrated with all the tedious requirements that upper manglement had saddled him with that really had nothing to do with sales or electronics, or anything else in the real world. Which seems to be the way with most RS manglers these days.

Gee Reg, I thought it was common knowledge that the split cores had to fit around the conductor so that the two halves touch properly. If the "hole" is too small, that won't happen. The number of useful answers provided by this group grows less by the day.

Snip some more for brevity.

You must think that the supports are metal. They are not.
They are PVC and dry wood. Yes they would have some dielectric effect
but it would be very little compared to the skin effect shielding that we
should
see with this design. I indicated on the web page that skin effect
shielding
should add about 2 feet to the length of the antenna, and would lower the
resonant frequency by about 2.8 MHz.

The presence of the test meter between the plates would act to increase the
capacity between the plates but again by very little. The meter is 2 1/2
inches
wide and is about 6 square inches in cross section as seen between the disk
plates. If the meter were a metal box, then the effective spacing between
the
disk would be reduced by the width of the meter (2 1/2 inches) so the
spacing
for that area would be 7 1/2 inches. Because we are using a 12 inch
diameter
disk, the presence of the meter does not introduce a large change in the
final
capacity between the disk.

The calculated capacity between the disk without the presence of dielectrics
or meter is 2.54 pF. This would have a reactance of about 2280 ohms at 27.5
MHz.
By using Eznec, it was easy to see that a reactance much lower than 2279
ohms
placed in parallel with the feed line had little effect on the resonant
frequency.
Those who have good skills in using Eznec should try placing a variety of
capacity
sizes in parallel with the feed line to see how the antenna impedance and

resistance change.

I completely agree that the physics must apply equally everywhere. That is why
I picked a thick disk (relative to coax braid). That is why the disk is 12 inches in
diameter, large enough to have a very measurable effect on the resonant length
of the antenna if the skin effect shield is real.

The disk antenna experiment has two radically different expectations between skin effect shielding
and widely accepted electromagnetic theory. Clearly the results of the experiment do not support
skin effect shielding which is troubling for all of us trained on the ARRL Antenna Handbook.

You two guys have completely missed the point.

I did NOT say dimensions and and permeabilty are unimportant.

I said it was more important to decide FIRST whether any cores were needed
at all.

Which I'm sure you will agree with. Or are your shacks and antennas
festooned with ferrite rods, rings and clamp-ons about which you know
nothing except their dimensions ?

In any case an exact fit is unnecessary.

Yours, Reg.

Hi:

There is no antenna with any reasonable or unreasonable combination of coils/traps or whatever that will work over that range. There is one antenna that might do the job for you. It's called an active antenna. Its a short whip, about 4' long, with an amplifier right at the base. The amplifier converts the VERY high Z of the antenna to match coax to the radio. It works by using the whip as a "capacitive probe" to the electric (radio waves) fields around the whip. They can be quite effective. The disadvantages are they can't be used for transmitting. Active antennas are quite propone to over load by strong local signals. And they pick up local noise like computer hash, ignition noise and power line noise very well.
But its the only antenna that will come close to doing what you want.

My first reaction to this proposal was that detection would be impossible under any circumstance. I was thinking of a torroid detector which surrounded the test device.

After further reflection on the proposal, I think that direct coupling to the test box or capacity coupling could detect current inside the apparatus. This would be true because there would always be resistive caused voltage drop across the conductor.

But the test would only be convincing if it were conducted by two people, one who would be the builder and supporter of skin effect shielding, one who would be the observer and detractor of skin effect shielding. If the detractor built and performed the experiment, the supporter could always say negative things such as the power level was too high, the shield was too thin to be effective at the frequency used or the seal of the box was not complete. If the supporter built the apparatus, the detractor would use every means possible to detect the current inside including amplification and direct attachment to the apparatus. It would be a real challenge to prevent any detection by the detractor unless the power level inside was zero. Of course there would always be a lower detection limit due to noise but the limit could always be overcome by increasing the power level inside the apparatus.

How do you think the results of the disk antenna experiment should vary when we first assume skin effect shielding occurs, and then assume that the fields act without skin effect shielding. I concluded that the resonant frequency should be about 2.8 MHz lower that what was observed. What would you predict?

You mean the EPA actually did something of benifit? Last I heard they were killing spray cans because of the sun causing holes in the ozone area...he he.

Hi Richard,

At 1/2 WL spacing above ground there will be a null directly overhead and a beam peak near 35 degs. At lower heights it will radiate straight up but coverage at low elevation angles will be very poor. I was just wondering what perceived advantage there is supposed to be using a horizontal loop versus a patch or crossed dipoles for GPS applications.

It would be nice if people would read the question. What Floyd asked for
was "does anyone know where he can buy the 3/8 types". That's all he
asked. Now, half a dozen messages later, no-one has answered his question.
Floyd, I don't know. I was hoping someone would, as I am interested also.
Good luck.

If your results are unexpected, "skin effect" is not the fault.

Skin effect is proven everywhere by shields that work.

Skin effect is proven everywhere by metal sheets inpenetrable to r-f.

Skin effect is proven everywhere by predictable r-f resistance which increases with the square roots of the resistivity of the metal, the permeability of the metal, and the frequency of the operation.

Indictment of skin effect for failure of an experiment is a "bum rap".

yep thats the one. Makes my old NEC WIN PRO look complete crap by comparison.

I've run a few tests on it and it seem fine.

Far more intuitive interface than anything I've seen.

I've had experience of IE3D,NEC various versions,and FEKO but for typical use for those of us that want to get the job done at home this MMANA one look like just the ticket.

And when a magnetic field indicating current on a coaxial line is found, a
return current must be flowing on the outside of the braid (separate from
the current on the inside of the braid) for how else would a field
penetrate the skin effect shield.

So why does a short piece of metal not connected at the ends fail to contain
electrical or magnetic fields?

Steve, VE9SRB wrote:
"---what perceived advantage is there to using a horizontal loop versus a patch or crossed dipoles for GPS applications?"

I have no experience with satellite antennas. The ARRL Antenna Book suggests an assortment of antennas to select the best for reception of the satellite at the moment. It includes a turnstile, rotary dipole, and a horizontal loop. It is shown on page 19-8 of the 19th edition.

I agree that the horizontal loop should likely be less than 1/2-wl above its reflecting surface to avoid a null overhead.

The crossed dipoles with a 90-degree phase delay between them produce circular polarization and are an omnidirectional array.

The loop ia an omni, but is horizontally polarized as specified.

The dipole best receives signals which are perpendicular to the wire.

The antenna has more information and references.

Best regards, Richard Harrison, KB5WZI

Jereon,
As you've already seen from the other replies, a
single antenna for the range of frequencies you wish
to cover is a bit unrealistic. That is, if you want
an antenna that works well over that whole range. If
you are willing to use an antenna that does NOT work
well over that whole range of frequencies, then that's
a different story! In that case, any antenna, as long
as possible, should work (not well, but it will work).
The type of mount for that antenna would depend on how
large the antenna is, some are too large for a magnetic
mount, which depends on the size/strength of the magnet.
Good luck, and I would be interested in what you do
use as an antenna...
'Doc

Roger, W7WKB wrote:
"So why does a short piece of metal not connected at the ends fail to contain electrical or magnetic fields?"

An effective shield must block both fields. A Faraday screen blocks the electric field but is a sieve which allows the magnetic field through. It (the magnetic field) instantly regenerates an electric field and the perocess is practically lossless.

A capacitance can pass an electric field while blocking the magnetic field.

A shield may be too small or it may be ineffectively earthed.

Oh really? MMANA is better than an NEC2 based interface? Man, you've
got to be smoking wacky tabacy.

Tell you what why don't you model the K8CU LDPA in the current issue
of QST magazine and show me where MMANA's results come any where near
those published in the article? Don't be concerned that the author
mentions that MININEC will not model the antenna properly because
there are current versions that will - such as Antenna Model but, of
course, Antenna is not a free program. Maybe you get what you pay for?

"VE9SRB" <srbest@att.net>
shared these priceless pearls of wisdom:

I was just wondering
->what perceived advantage there is supposed to be using a horizontal loop
->versus a patch or crossed dipoles for GPS applications.

Aerodynamic advantage in that the radome may be made a bit smaller than a turnstile (crossed dipoles) which requires a quarter-wave matching section out in the breeze. Construction advantage for the patch in that trying to tell Harry Hamhand out in East Undershirt with nothing more than a kerosene powered soldering burner how to make a patch is a nontrivial problem. Loops out of #18 wire with noncritical spacing to the ground plane looked like a decent solution.

However, if you've got something that you would like to have me try, I'm certainly open to suggestions. The application is an external GPS antenna for light aircraft, a magazine article describing the construction of them, and a few measurements with very crude equipment as to how well each of them is perceived to do the job relative to a commercial standard.

>final
>capacity between the disk.
>
a = 10

A = pi * rï¿½ = 113
C = (0.225 * A)/(a * 10ï¿½ï¿½)
= 2.54 pF

a = 7.5
A = pi * rï¿½ = 113
C = (0.225 * A)/(a * 10ï¿½ï¿½)
= 3.39 pF

The difference being +33.5% error of course, negating the false
illusion of accuracy.

>
>Those who have good skills in using Eznec should try placing a variety of

>I picked a thick disk (relative to coax braid). That is why the disk is 12
>inches in
>diameter, large enough to have a very measurable effect on the resonant
>length
>of the antenna if the skin effect shield is real.

All of which has nothing to do with applying physics equally
everywhere. As such the statement above adds nothing and ignores this
requirement. To conform to the demand of this universal application
requires you to repeat your tests by moving the disks out and away
from the drive point while at the same time exhibiting identical
results. This is wholly lacking in your work and no amount of
rhetoric will replace it.

If you do in fact perform this task, by degrees (that is, displacing
the disks by increments of, say, 12 inches) until the disks are found
at the remote ends; you will undoubtedly find the conventional
expectation of the dipole becoming electrically longer is satisfied.
If you still observe otherwise, we can tackle that in earnest to shake
out those errors.

>
>Clearly the results of the
>experiment do not support

>73, Roger, W7WKB

Hi Roger,

Clearly the results, measurements, and revisionist ideas are entirely out of whack. Your results don't even offer the appearance of tracking your own theory. Statements of differences being negligible have been shown to be off the mark by considerable (and quite obvious) margins.

The most troubling aspect is the inappropriate use of a software model and the corresponding blind-side of not simply attaching a 2.54 pF OR 3.39 pF cap across the standard dipole's drive point connection for measurement to test the assertions made. This step cannot be argued to be prohibitive in the face of adding two significant structures that would take far more effort (and which effort has obviously been expended).

The conventional teachings of skin effect remain standing quite securely.

Looks like you need to do something different. I have offered two compelling things to do.

A small piece of brass sheet suspended over a ground plane and fed (and matched) with a single connector may not be as big a problem for Harry as you think. Feeding and matching a patch is probably easier than feeding and matching the loop.

There is a new Ham Radio Portal online at

http://www.hamradio-portal.com

This Portal contains news, Information and

special topics like Echolink software and many more.

It has a Weblink and download database.

A new Webboard to discuss topics is also there.

You can also submit news and topics what

comes available on the top of the page!

It should not to be in compete with other Portals.

Just a new one with a new look and nice features.

We hope to see you there!

4879. safety ground and antenna ground - tie together and connect to A/C ground?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-10 17:39:28 UTC
From: Andreas Hofmann <andreash23@hotmail.com>
Message-ID: <3d7e2e50$1@news.microsoft.com>
Source record: 134917

Hi,

I have a dipole and once it enters the house, it is routed through a lightning surge protected coax switch. This allows me to ground the dipole (and all other antennas) if I dont use the station. Let assume I do not need a RF ground.

1. The coax switch's case needs to be tied to the house's ground. Is it enough to just connect it to the neutral wire in the nearest power receptacle?

2. All the equipment's grounds should be tied together and connected to the house's ground as well. Can I just connect them to the coax switch's ground (if answer for 1 is yes)?

Thanks

Andreas, KU7T

Also, anyone interested could get in touch with Amidon or Bytemark and see if
they still sell
"Round Cable Suppression Cores" which are split cores for cables with diameters
of from .1 inch to
.59 inch. Nylon housing sold separately.

I purchased a used CA-UHV and I am using an MFJ 259B to "tune" the antenna. I found an issue on 2 meters and was looking for some feedback.

1) The lowest SWR seems to be down around 141 MHZ. As I approach 146 MHZ, the SWR reaches 3:1. It seems like the whip was trimmed too short. Am I correct in this thinking or is it too long?

2) If the wip is too short, does anyone know what might be a good replacement material for the whip if I wanted to replace it with a longer whip to bring the antenna back up to 146 Mhz?

3) I wanted to build a few stinger antennas for the coils, the ones with the small ball at the end. Carrying on from question two, where might I get the material for this a stinger? I have also heard that some solder can be used to form the ball at the end of the whip.

You've got it reversed. The antenna is too long. Make it shorter, and the point
of resonance will move to a higher frequency.

And skin effect can be proved to occur on *any* conducting surface that has RF current flowing on it, for *any* reason. It is not limited to any particular shape of conductor, or to any particular circuit configuration that makes the RF current flow. The proof is reproduced at:
http://www.ifwtech.co.uk/g3sek/misc/skin.htm

The math and physics are pretty high-flown but they do prove the skin depth equations for the general case, which I haven't seen proved anywhere else.

That means that wherever you postulate RF current, you also need to postulate that it flows only (or nearly) on the surface. Whatever else you say about the system under consideration, it has to be consistent with the existence of skin currents... and this is a very powerful way of determining how a wide range of RF circuits behave.

>
>In the present context, what is R.

The R that effectively appears across the trap tuned circuit is radiation resistance, which represents the loss of energy from the antenna by radiation (with a small correction for loss of energy in the components themselves, represented by their unloaded Qu's).

Note (but not for Reg, who already knows) that the effective radiation resistance as seen across the trap is not the value you measure at the feedpoint. It is transformed to higher values as you move along the antenna element towards the open ends.

I don't think the "loaded Q" concept should be pushed too far, but it does give a way of understanding the relationship between the Qu's of the individual trap components and the energy loss in the traps when they are operating.

H Andreas:

You should put in a separate ground rod for the station as close to the station as you can get. Then connect the coax switch to that rod and then a separate wire should also connect from that rod to the ground at your electrical service panel (the heavy copper wire that comes in from the ground rod to the box). The wire should be at least #t6 bare copper wire. In my area this is what is required by code. If you use the receptacle ground,and your hit by lighting, at best the wire to the shack from the electrical panel and all the radio's etc. hooked to that circuit will be destroyed, at worst your house will burn down.
This no place to play around and look for the easy way out.

Hi Bill,

Quadfilar means that four (4) wires are wound together, in parallel.
Your drawing needs color for each winding to clearly answer your
question, also, it needs phase dots on the schematic to correlate
correct connections. 1 & 3 appear to be backwards, as do 5 & 7; but
without the individual windings visible, or phase information, it is
difficult to say.

What you have in your mind, and what you have posted may well work,
but without these details, I for one, could not respond in the
affirmative. Reasons for my saying 1 & 3 appear to be backwards is
due to all windings starting at the same end (presumably 1,4,5,8)
would not find 1 & 3 in proximity with 2 & 4 connected unless there is
a phase inversion not shown. [Same goes for 5,7 and 6,8.]

Is the quote you're referring to the one Richard posted recently:

The 19th edition of the ARRL Antenna Book says on page 23-2:
"In good conductors the speed (of r-f wave travel) is so low that the
opposing fields set up by the wave front occupy the same space as the
wave itself, and thus cancel it out. This is the reason for "skin
effect" in conductors at high frequencies, making metal enclosures good
shields for electrical circuits working at radio frequencies."

If so, that's not at all what it says. It doesn't address the issue of currents on opposite sides of an open plate at all.

If you're truly interested in what respected authors have to say about skin effect, here are some quotes I originally posted in this group on August 30, 1996. The topic was "Re: BALUN necessary for a dipole", and anyone interested in the current thread might be interested in that discussion also. More than 300 postings were made. Anyway, here are the relevant quotes:

Introduction to Electromagnetic Fields and Waves, Charles A. Holt, Dept. of Electrical Engineering, Virginia Polytechnic Institute, p. 187:

The electric field inside a perfect conductor is zero, for otherwise there would be the absurdity of an infinite drift current. We know from Maxwell's equations that time-varying electric and magnetic fields always accompany one another and, consequently, a time-varying magnetic field cannot exist in a perfect conductor. An electric field always has a magnetic field

according to the Maxwell-Ampere law. As time-varying magnetic fields cannot exist in perfect conductors, neither can time-varying electric currents. However, we know that good conductors readily carry alternating currents. Clearly, the time-varying current of a perfect conductor must reside on the surface, in a layer of zero thickness.

Engineering Electromagnetic Fields and Waves, Carl T.A.Johnk, Professor of Electrical Engineering, University of Colorado, Boulder, p. 130:

Case B. One region is a perfect dielectric; the other is a perfect conductor. Electric currents are limited to finite densities in the physical world. Thus from (3-7) J = <sigma>E, the assumption of a perfect conductor in region 2 of Figure 3-4 (<sigma> -> <infinity>), implies that E2 in that region must be zero if the current densities are to have, at most, finite values. Moreover, with electromagnetic fields satisfying (2-108), <del> cross [complex]E = -j<omega>[complex]B, one can see that if E2 is zero in region 2, then [complex]B2 must be zero there also. Thus for time-varying fields, <sigma> -> <infinity> implies E = B = 0 in a perfect conductor.

Electromagnetic Energy Transmission and Radiation, Richard B. Adler, Professor of Electrical Engineering; Lan Jen Chu, Professor of Electrical Engineering, and Robert M. Fano, Professor of Electrical Communications, all of the Department of Electrical Engineering, Massachusetts Institute of Technology, p. 11:

[All vector quantities] . . .inside medium 1 we must put E1 <identically equal to> 0, for the specific reason discussed above. Therefore, D1 = 0 (Eq. 1.20a) and <rho>1 = 0(Eq. 1.15a) Also, <the partial derivative of B1 with respect to t> = 0, by Eq. 1.15b, and of course <the partial derivative of D1 with respect to t> = 0. . .

We are forced to conclude that all time-varying fields inside a perfect conductor are certainly zero, and that even a static electric field cannot exist in it.
> . . .
>

The voltage drop would be more from reactance than resistance. It would exist even for a perfect conductor.

> But the test would only be convincing if it were conducted by two people,

> but the limit could always be overcome by increasing the power level inside
> the apparatus.

I'm personally satisfied by the fact that the knowledge about skin effect is completely consistent with all carefully done experiments, and is based on principles used daily to design and use a very diverse group of devices which work as predicted. Considering this base of accepted knowledge, it's silly to ask for further "proof". Sorry, the burden of proof is strictly on the person who makes claims contradicting a couple of centuries of successful theoretical and engineering work.

I remember my days as a technician, where every now and then measurements would seemingly show that the sum of currents flowing into or out of a junction didn't add to zero. Quite a large number of fellow technicians didn't have a sufficient theoretical or educational background to trust the validity of Kirchoff's current law, and each time were convinced they had "proof" that it was invalid. The same happened from time to time with Ohm's law. I ended up spending a good deal of time finding the flaws in their measurement techniques, which is what they should have done.

When your experiment contradicts a couple of centuries of self-consistent and successfully applied knowledge, you shouldn't waste your time or ours asking for additional "proof" that the existing theory is invalid -- you should spend it finding out what assumptions you made were wrong, or what measurements were invalid. And you'll find that, gee whiz, all those guys maybe really do know what they're talking about and maybe a back yard experiment isn't really rigorous science. And you'll learn from it.

> How do you think the results of the disk antenna experiment should vary when
> we first assume skin effect shielding occurs, and then assume that the
> fields act without skin effect shielding. I concluded that the resonant
> frequency should be about 2.8 MHz lower that what was observed. What would
> you predict?

I don't know. With all the interacting fields, it's too complex a problem for me. You might try modeling it with EZNEC or the program of your choice, using radial wires to represent the disk -- the model radial wires wouldn't exhibit skin effect. Or you can re-run your experiment with the disks replaced by a reasonably sparse structure of radial wires. But I wouldn't even try to draw any conclusions from this

experiment because of its complexity -- I'd do something like the shielded box or coax experiment (if I needed additional convincing about skin effect -- which I certainly don't).

The quotes I just posted address that question. To understand it at a deeper level, you'll have to learn more about electromagnetic fields.

Hi Bill,

No inconvenience at all, you came more prepared than most who have
grand designs of naming an antenna after themselves. You might also
include what you are going to use this for - it could be significant
to consider in light of that application. And you never know, someone
else might chime right in with a less equivocal (and still correct)
answer than mine.

Andreas,

Get QST. A series was run for 3 months (June, July, Aug ?) on this topic. It is worth it's weight in gold. Written by Ron Block, a ham, and a Polyphasor employee who really knows his stuff. You have a lot to consider.

>It might not work quite so well for me and Andy in Europe, since our
>bands are only 3.5-3.8MHz and 7.0-7.1MHz.

Actually, the Region 1 situation is "easier" for the W3DZZ because the bands
are narrower ;-)

> For optimum performance, the
>trap resonance needs to be moved down to 7.05MHz, and the L/C ratio
>changed, together with the two wire lengths. Apart from that, our trap
>dipoles are exactly the same as yours :-)

Hmm - let's take a look at that...

Use the resonance formula LC = 25,330/f^2, where F is in MHz, L is in uH and C
is p.

Rewrite the formula as:

f = sqrt (25,330/LC)

For 62 pF and 8.2 uH,
LC = 508.4
(25,330/508.4) = 49.823
f = sqrt(49.823) = 7.0585 MHz

So the W3DZZ design is almost on 7.05 as-is. W3DZZ seems to have tried to
optimize the antenna for the middle of the US amateur bands as they were in
1955.

In a later article, a version optimized for the US phone bands used more C and
less L (approximately 100 pF C). It seems logical that a "Region 1 W3DZZ" would
use maybe 50 or 56 pF capacitors and suitable inductors for resonance on 7.05
MHz.

Of course with the advent of modeling software like EZNEC, we have it much
easier today than W3DZZ ever did.

There are also a lot of ham-oriented tech papers on grounding at the Polyphaser site that can be downloaded for free.

Hello all,

I'm getting some strange (13dBi gain at 15 degree azimuth plot) results when modeling a longwire four wavelengths long at 7 MHz... The antenna is 280' feet long at a height of 5'. Make it any higher and the gain decreases. I'm assuming the software (Elnec 3.07 for DOS) cannot model wires close to the ground? Any suggestions?

Thank you,

Ken N4VSD

The Latest in Multi-Band Vertical Antennas

by John, K3CT

Cushcraft and Hy-Gain have recently released new multi-band vertical antennas with improved efficiency and operation on all amateur bands from 6 meters to 40 meters. The model numbers are Cushcraft R8 and Hy-Gain AV640. Hy-Gain also sells the AV620 without the 30m and 40m bands. These antennas all share a similar design which solves many problems that plagued the older generations of multi-band vertical antennas.

Prior to the WARC bands multi-band vertical antennas covered 40m, 20m, 15m, and 10m usually with a multi-trapped ½ wave element. Users seldom installed these antennas in the clear or with the proper ground radials. These factors contributed to these antennas earning a reputation of being poor performers with narrow bandwidth. When the WARC bands became available, the manufacturers simply added more traps without thinking much about the performance. Both the bandwidth and the efficiency suffered due to the added traps.

The next generation of multi-band verticals, I believe pioneered by Cushcraft, addressed the radial issue by end feeding a ½ wave element. In this design, the ½ wave radiator was shortened with inductors in the traps to make the length manageable. This antenna contained the same number of traps so the overall efficiency improvement may have been small.

Around the same time GAP antennas made a big splash in the market when they released their line of antennas without traps or radials. I know very little about their antennas except that they don't have a good reputation for being a rugged antenna.

This brings us to the latest design in multi-band verticals. After moving to a new QTH, I wanted to get back on the low bands quickly. I tried dipoles but I wasn't able to install them high enough to be effective for DX. My interest turned to verticals for their low takeoff angles and the R8 and AV640 caught my attention. After some research, I decided on the cheaper AV640 but it was out of stock. The R8 was in stock so it was purchased instead. After using this antenna for several months, I decided to reverse engineer the design. I started with a table of the element lengths and mounting positions.

The R8 and AV640 use similar designs to improve both efficiency and bandwidth when compared to the older generation of multi-band verticals. The number of traps was reduced by grafting four (trapless) elements onto the main vertical support for each of the bands 6m, 10m, 12m, and 15m. In these designs, the major vertical element is used for operation on only 17m, 20m, 30m, and 40m.

The efficiency was improved with multiple techniques. The radial requirements were greatly reduced by raising the feedpoint impedance. This allows an efficient antenna to be constructed with seven four-foot radials. The feedpoint point impedance was raised by end feeding 3/8 wave elements. Being slightly longer than a wave, these longer elements also have more gain than a shorter wave element of the earlier designs. The drawbacks of this design are twofold. First, a matching transformer is required to match the 50 ohm feedline to the approximate 1200 ohm feedpoint impedance of the 3/8 wave elements (the box at the bottom of the antenna) and second, the length of the radiators on the lower frequency bands grows beyond reasonable mechanical limits of a freestanding vertical element. For instance, a 3/8 wave 40m radiator electrically must be nearly 50 feet high! A vertical antenna this tall without guy ropes would be very difficult to install and maintain. Vertical antennas can be physically shortened with coils or capacitance hats. The latter is more efficient (no resistive coil losses) and both techniques are used in the design of these antennas.

The Cushcraft antenna length is 28.5 feet tall weighing 23 lbs and the Hy-Gain is slightly shorter and lighter at 25.5 feet / 17.5lbs. If you look at photographs of each of these antennas, you will notice that they differ near the top. The Cuchcraft R8 contains two traps, one shared on 17m & 20m, and two capacitance hats. The Hy-Gain AV640 being shorter has been designed with additional capacitance hats and/or additional inductance (series coils) to physically shorten the antenna by an additional three feet.

In less than two pages, I ve attempted to explain a brief history of multi-band vertical antennas and the basic design of the latest generation. Before considering the purchase of either antenna, please review the operating bandwidth of each. If you want to work DX and can t install a horizontal antenna high enough for low angle of radiation, consider a vertical!

ELNEC and other MININEC based programs can't be used to model antennas
with horizontal wires closer than about 0.2 wavelength from the ground.
If you try it, you get results like you reported. Please read the
"Modeling Ground" section in your ELNEC manual.

The only solution I know of is to use an NEC-2 based program like EZNEC.

4910. Trap L/C Ratio and Bandwidth

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-11 08:43:58 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <almvodolh1@venus.btinternet.com>
Source record: 134851

ONE MORE VERY POPULARLY PLAGIARISED MISCONCEPTION.

Re-write the 'Bibles' !

It is not true antenna operating Q and hence bandwidth are dependent on trap L/C ratio.

The Q of any resonant system is always a ratio of reactance to resistance. In the present context, the resistance concerned is the radiation resistance seen looking back from the trap into the end of the dipole wire. RadRes depends on length and diameter of the antenna wire and the frequency.

Trap L and C are *predermined* by the overall length of the antenna, the length of antenna beyond the trap, and the two (sometimes three) frequencies at which the antenna is required to be resonant. Their ratio is nowhere involved, only their product.

At the trap frequency Q = (Radiation resistance)/(Reactance of L) approximately

and the bandwidth for which SWR = 1.5 is 0.41 * MHz /Q.

This bandwidth has to be accepted - for given antenna dimensions there's nothing which can be done about it.

Intrinsic coil Q is so high it can be neglected. Its only use is in estimating power lost in the coil.

So although the L/C ratio exists in a trapped antenna it is of no practical value. Nothing else can be calculated with it. It is not possible to work backwards from it. It is like the human appendix for which nobody has yet found a use. It does help to fill space between advertisements in the periodicals and add to the SPAM on the already overloaded Internet. ;o)

On the other hand, SWR vs frequency presented to the transmitter (which is what really matters) may depend more on the characteristics of the transmission line plus tuner than on the much criticised antenna. Which is why I have not included antenna bandwidth in program TRAPDIP. It could be misleading.

Program DIPOLE3 models the whole system (no traps) from antenna to transmitter via twin-line + balun + coax + tuner. Unfortunately the SWR as seen by the transmitter is always 1:1 because as frequency is varied the tuner L and C components are re-calculated and reset to ensure SWR actually is 1:1. Bandwidth at the transmitter cannot be displayed..

Source record: 134852

From a practical standpoint, the ground should be as short as possible. I normally use a piece of heavy braid to a ground stake just outside the shack.

When you have lighting induced voltage, the current will follow the path of least resistance. If grounded to the ground pin of your wall socket it must travel the length of the wire back to the house ground. The wire is rarely a straight run. Lighting is not real happy making right angle turns and usually leaps out at some point causing damage.

The short braid to ground makes the electrons happy and protects your equipment. If you take a direct hit, under some conditions nothing in the world will save the equipment. The more practical case is induced voltage from nearby strikes, these are easily taken care of by the braid.

If you want to get a feel for what you are dealing with, disconnect the coax and let it lay on a table when a storm is at least 20 miles away. Note the neat arcs between the center pin and the shell...

My last direct strike totally melted half of my 75 meter dipole and the coax, jumped out of the coax rolled on the floor burning a hole in the rug, proceeded to the electrical wiring, then up to the attic to the far end of the house where it decided to exit, it blew off a piece of plastic siding and down a wooden post to ground.

The best lighting protection against direct hits is full replacement coverage insurance. While it is relatively easy to protect tower mounted beams, a dipole hung between two trees is very difficult to protect with absolute confidence. The only really safe method is to disconnect all the antennas and lay the coax connectors on the ground in the yard. Not very practical when your as lazy as I am.

Before we rush out and rewrite the Bibles. . .

The overall length of the antenna is *predetermined* by the trap L and C. This is just as valid a statement as the reverse, and probably better represents the way most amateurs go about trap antenna design. And the Q of the system is a function of the length of the antenna. So, once you choose the L/C, you've determined the bandwidth -- as well as the antenna length.

Just another old wife,

Roy Lewallen, W7EL

Is this really an adequate solution for the risk of personal injury or death?

It seems that a commonly held view is that protection of life is not part of the issue.

A bit late with my answer here.
I have talked to St Thomas (U S Virgin Islands) on 20 meters.
I'm in the San Joaquin Valley in California.
I live in a mobile home here, 14 X 65, and have my 40/20 dipole entirely
over the roof.
run diagonally, and even bend ends if you need to.

Yes.

>Trap L and C are *predermined* by the overall length of the antenna, the
>length of antenna beyond the trap, and the two (sometimes three) frequencies
>at which the antenna is required to be resonant.

That is true, but misleading, because you can also choose to vary the
length of wire beyond the trap in the interest of improved bandwidth.

>Their ratio is nowhere
>involved, only their product.
>
Not true. The product must obviously be kept constant because it
determines the resonant frequency of the trap. But different values of
L/C can be used (while keeping the product L*C constant) - and that
will determine the wire length required to give resonance on the
lower-frequency band. Those choices *will* affect the SWR bandwidth on
that band.

>At the trap frequency Q = (Radiation resistance)/(Reactance of L)
>approximately
>
That is the operating Q of the trap - on its own.

>and the bandwidth for which SWR = 1.5 is 0.41 * MHz /Q.
>
But that's a different Q - the operating Q of the whole antenna, as
measured at the feedpoint. That Q is determined by the properties of
both the trap and the rest of the antenna.

So don't burn the Bibles yet.

And don't assume that people who agree with the handbooks are plagiarists. The other possibility is that they've done their own thinking, and only agree because the handbooks got it right.

Fred Hambrecht repeated an often stated misconception:
"If you take a direct hit, under some conditions nothing in this world will save the equipment."

True, because "some conditions" is undefined.

False, because thousands of commercial radio stations of all types are in the most salient spots. They take tens or hundreds of direct hits every year and suffer no damage. In fact their 24-7 operation is affected almost imperceptibly.

Lightning protection is not always perfect in all commercial stations. One posting in this newsgroup identified a medium wave broadcast station burnt to the ground by a lightning strike. That is the only instance I`ve heard of.

I`ve worked in a number of broadcast stations since 1949 . These had countless direct hits. The worst that ever happened was loss of a few seconds air time while the transmitter cycled off then back on to clear the overload caused by the lightning.

I had a waveguide switch coil burnt by lightning in one of hundreds of microwave repeaters I`ve been associated with, but I easily fixed that exposure.

It is complete baloney to say you can not protect against a direct hit.

Best regards, Richard Harrison, KB5WZI

Not just yet.

> It is not true antenna operating Q and hence bandwidth are dependent on
trap
> L/C ratio.
>
> The Q of any resonant system is always a ratio of reactance to resistance.

The Q of a resonant system is not 0.

> In the present context, the resistance concerned is the radiation
resistance
> seen looking back from the trap into the end of the dipole wire. RadRes
> depends on length and diameter of the antenna wire and the frequency.
>

Antenna Q is not determined from the resistance looking from the trap back
into the antenna wire.

In regards to the trap, the R, L and C properties of the trap will provide
an indication of the Q of the trap itself and not the antenna system.

For the antenna system, Q is a function of the antenna's feedpoint impedance
properties which are a function of the antenna's R, L and C properties and
the translation of the trap's R, L and C properties to the antenna
feedpoint.

For the resonant antenna, Q is not equal to X/R. At resonance X = 0 which,
from the X/R formula, implies that Q = 0 at resonance. It is not. For an
antenna, determining Q from X/R is only approximately valid for very high
values of Q, where X >> R. This generally applies at low frequencies where
the antenna is small.

Near the antenna's resonance, a different method must be used to determine
antenna Q. One method is to determine Q from the antenna's 1/2 power
impedance bandwidth as follows:

Q = 2 / BW

where BW is the bandwidth determined from the 1/2 power SWR points where the
ZO used to determine SWR is the antenna's feedpoint resistance. The 1/2

power SWR is equal to 5.828.

Another method is to determine Q directly as follows:

Q = A (B + C)

where A = w / (2 R), w = 2 pi F

B = dX/dw

C = |X|/w

> Trap L and C are *predermined* by the overall length of the antenna, the
> length of antenna beyond the trap, and the two (sometimes three)
frequencies
> at which the antenna is required to be resonant. Their ratio is nowhere
> involved, only their product.
>
> At the trap frequency Q = (Radiation resistance)/(Reactance of L)
> approximately
>

Is this supposed to be the Q of the trap or the Q of the antenna? In either
case, this formula is not valid. Q is never approximated by Resistance /
Reactance.

> and the bandwidth for which SWR = 1.5 is 0.41 * MHz /Q.
>

This is not the correct relationship for Q and bandwidth.

Andreas, KU7T wrote:
"The coax switch`s case needs to be tied to the house`s ground. Is it enough to just connect it to the neutral wire in the nearest power receptacle?"

The nearest power receptacle provides a safety ground (if the receptacle is the 3-wire type). This safety ground is to avoid shock from the power service and is inadequate for lightning protection. The impedance of the safety wiring is too high given the possible magnitude of the lightning strike. The safety wire is separate from the neutral wire until it reaches the distribution panel.

A ground rod (or better ground) is needed where a transmission line enters a house. If that spot is not also where the power service ground connection is, the radio ground rod must be connected by a no. 6 copper conductor (or better) to the power service ground connection. This interconnection is a code requirement in most jurisdictions.

All the radio equipment should be connected by a short direct connection to the external ground established for the coax. The idea is to minimize the difference of potential between all pieces of equipment. Conductors have inductance in addition to their resistance and lightning is a transient which produces a-c across the spectrum in addition to its d-c component. Conducters at the same potential don`t flash across.

Best regards, Richard Harrison, KB5WZI

It depends who "you" are.

"You", in your purpose-built commercial station, certainly can protect against a direct hit.

"You", in your amateur station with a grounding system that was not purpose-designed, and utility wiring coming in here, there and everywhere, stand much less chance.

For "us" amateurs, the best option seems to be a balance between reasonable precautions and keeping the insurance paid-up. The right balance depends on the installation and the local risk of lightning.

U.S. SUPPLIES, CALIBRATES AND ENDORSES

USE OF CHEMICAL WEAPONS IN IRAQ

As the Bush administration works to gain world support to conduct a pre-emptive strike against Iraq, new disturbing information has surfaced with regard to U.S. involvement in the development of Iraqï¿½s chemical and biological weapons program.

The pre-emptive strike is based upon President Bush and Vice-President Cheneyï¿½s beliefs that there must be an invasion of Iraq because Saddam Hussein:

1. possesses weapons of mass destruction and the potential for nuclear weapons,

2. used these weapons on his own people (Kurds) and the Iranians,

3. has a history of lying to the world.

According to information obtained by the AGWVA, there is irrefutable evidence to show that the Unites States government provided and encouraged Iraqï¿½s use of chemical weapons. The United States Department of Commerce and The American Type Culture Collection (ATCC) provided at least 80 shipments of biological agents that were not attenuated (or weakened) and were capable of reproduction. These shipments included such virulent agents as Anthrax, West Nile Virus and Clostridium botulinum (S.R.103-900, May 25, 1994, pg. 264).

The AGWVA also found it very disturbing to learn that on December 19, 1983, the Middle Eastern envoy who carried a handwritten note from President Reagan to Saddam Hussein, to ï¿½resume our diplomatic relations with Iraqï¿½ was none other than our present Secretary of Defense, Donald Rumsfeld.

According to ï¿½U.S. Diplomatic and Commercial Relationships with Iraqï¿½, 1980-August 2, 2000, (www.cam.ac.uk/societies/casi/info/usdocs/usiraq80s90s.html), Nathaniel Hurd states:

ï¿½Iraq reportedly began using chemical weapons (CW) against Iranian troops in 1982, and significantly increased CW use in 1983ï¿½ Shortly after removing Iraq from the terrorism sponsorship list, the Reagan administration approved the sale of 60 Hughes helicopters. Analysts recognized that ï¿½civilianï¿½ helicopters can be weaponized in a matter of hours and selling a civilian kit can be a way of giving military aid under the guise of civilian assistance.ï¿½

Mark Phythian, in his book Arming Iraq: How the U.S. and Britain Secretly Built Saddamï¿½s War Machineï¿½ (Northeastern University Press, 1997) stated:

ï¿½ ï¿½the Secretaries of Commerce and State (George Baldridge and George Shultz) lobbied the NSC (National Security Council) advisor into agreeing to the sale to Iraq of 10 Bell helicopters, officially for crop spraying. It is believed that US-supplied choppers were used in the 1988 chemical attack on the Kurdish village Halabja, which killed 5000 people.ï¿½

In his own book Turmoil and Triumph: My Years as Secretary of State, George Shultz refers to a declassified CIA report which notes Iraqï¿½s use of mustard gas in August 1983, giving further credence to the suggestion that the State Department and/or the National Security Council (NSC) was well aware of Iraqï¿½s use of chemical weapons at this time. If the use of chemical weapons was known in August of 1983, and Donald Rumsfeld went to Iraq in December of 1983, he was on notice that this country was using and was going to continue to use weapons of mass destruction. Why, then, did the United States move to de-list Iraq from those considered to be terrorist nations?

On March 23, 1984, Iran accused Iraq of poisoning 600 of its soldiers with mustard gas and Tabun nerve gas. Donald Rumsfeld returned to Baghdad on March 24, 1984. On that same day, the UPI wire service reported that a team of UN experts had concluded that:

ï¿½Mustard gas laced with a nerve agent has been used on Iranian soldiers. Meanwhile, Donald Rumsfeld held talks with foreign minister Tariq Aziz.ï¿½

Probably the most critical piece of information is that according to Washington Post journalist Bob Woodward, in a December 15, 1986 article, the CIA began to secretly supply Iraq with intelligence in 1984 that was used to ï¿½calibrateï¿½ mustard gas attacks on Iranian troops.

It is public record that the U.S. not only armed Iraq from 1983 thru August 1, 1990, but that they also provided the money to Iraq to purchase the weapons via the Atlanta branch of the Banca Nazionale del Lavoro (BNL), George Bush, Sr., and the Export-Import Bank. Iraq received $5 Billion dollars funneled through the Commercial Credit Corporation ostensibly for food credits. It is also public information that at least $2 Billion dollars from the defaulted loan was repaid by the U.S. citizen taxpayers.

Joyce Riley, spokesperson for the American Gulf War Veterans Association has for seven years been shining the light of accountability on the Department of

Defense for having armed our ï¿½enemyï¿½ with weapons of mass destruction, exposing our military to these weapons and then denying not only their culpability but the very existence of the mystery diseases. She often quotes Senator Donald Riegle (D-MI) who stated in Senate Report 103-900, ï¿½Our troops are not just sick, they are dying.ï¿½

Riley, a former Captain in the United States Air Force Reserve and Flight Nurse states: ï¿½If it wasnï¿½t bad enough to watch our troops become ill from our own weaponsï¿½ the Department of Defense labeled our sick men and women as ï¿½mental cases.ï¿½ These proud men and women have been abandoned, are now sick and must fight the battle alone. These needless illnesses and deaths now lie at the feet of the Pentagon and Veteransï¿½ Administration Hospitals.ï¿½

Steve,

With a rectifier in series with the meter, one could only expect what appears to be DC, no? That is, the current is all in one direction because of the rectifier. If the fluctuations are rapid enough to be integrated / averaged out by the dynamics of the meter (it can only move so fast) then the one-way current will appear to be a constant current.
From your earlier measurement, where the "meter went nuts" it appears that the circuit current isn't normally DC.

Also, one wouldn't necessarily expect to see current in this type of measurement when the transmitter is keyed. This is because an ideal situation would have all of the current flowing through the power source. The ground connection provides a potential reference so that there aren't potential differences between various equipments. Ideally there's no current flow. Less ideally, you need to consider what would possibly be conducted in the ground wire. If there is RF current, the rectifier may not be adequate to act as a rectifier at the frequency in question. The antenna has a lot to do with RF current possibilities.

If you put the 1KW transmitter in an automobile, do you expect to have high potentials (and the possibility of high current flow) from the car body to ground? Again, could depend on the antenna arrangement - vehicle integral whip vs. an external Yagi grounded through a pole.

Source record: 134770

My beverage antennas can't be replaced, so I'm considering some
alternatives as the 160 mx dx season approaches. I am particularly
interested in the 2 loop K9AY. But, then there are the flag, pennant
and ewe antennas to consider as well. Has anyone done any comparative
work on these vs. the K9AY. I know that the medium wave and longwave
listeners are particularly enthusiastic about the K9AY, but I haven't
seen much about their use on 160, despite the fact that they were
originally described for that band. I would be very interested in
hearing from K9AY users who have also used other "listening" antennas
and can offer some of the pros and cons. Thanks.

I agree.

There exist for most situations a range of treatment options and associated residual risk, whether it be a commercial, military or ham installation. One needs to consider the range and choose an option that provides the best value for one's own circumstance, consistent with local regulatory requirements which may stipulate requirements. (For example, the installation of earth electrods for communications equipment and the equipotential bonding is dealt with specifically in our electrical wiring standard and standards for lighting mitigation.)

There has been a tendency in these parts of recent years for people to depend on insurance and to not excercise prudence in their actions. The result of this is unsustainable insurance where people with insurance take risks without care, rusulting in claims that make premiums unaffordable, and in some cases here, collapse of insurers. Perhaps one needs to insure against the risk of collapse of your insurer!

I have seen some interesting write-ups of insurance claims for lightning damage to ham equipment and property that have run toward $100,000. I could imagine that it could easily exceed this if a serious fire is caused, or if personal injury or death was caused (either directly or indirectly (fire, falling antenna structures)), liability could be very big numbers. There is little doubt that in most situations a tall tower with sizeable conductors entering a residence increases the risk of lighting damage to the property or persons significantly. Might be that an insurer might regard an installation that was unsafe added to the risk and argue contributory negligence in the way that they would try to avoid liability if a bodgy electrical installation caused a fire.

Be responsible, consider the risk and manage it. It is a relevant technical aspect of the hobby.

How much space do you have???

I have just entered the hobby also and saw a web site that gave me this formula to make a dipole type, which basically 2 lengths of wire.

e.g.

```
|---------------------------| |---------------------------|
31.2ft 31.2ft

___________________ ___________________
| |
Centre > < Screen
|

'-------------------------------------------------Off to radio
```

This was from the formula 468/freq(Mhz)

468/15Mhz=31.2

As you probably know, the main sw band is approx 0 - 30Mhz so this, if I am correct should centre around 15Mhz

I could be wrong but I am sure I will be told on here. :-)

Anyway, if you make a long wire jobby, just be sure to insulate the ends and weatherproof the centre join.

I find PSK31 is interesting around the 14.07Mhz mark. You will need some software but it is plentiful on the net. Search PSK31 and hey presto.
In fact, I have it here in a zip file if you want it.

I had a 30ft length of coax inner (1 length) straight into my scanner, which isn't best suited to the task but nevertheless I got a signal from poland :-)

I hope I have been of correct assistance and happy listening.

Jerry.

YES! And anyone who believes he can hang a few Polyphasers, with their
ground wires connected properly, and escape all lightning damage, is kidding
himself.
Lightning and all that goes withit is a complex matter.

Your use of the 7.5 inch distance across the entire disk surface considerably overstates the actual change in effective distance due to the introduction of a conductor between the plates.

If a direct way is not built into Eznec, then we use the indirect way which works fine. I placed a small square loop coming from the location of the disk into the model. Then I used a variety of capacity values to see what happens to the antenna parameters. You could try this method.

Hi Richard,

I don't think I will do the different location experiment you suggest although it would be interesting to see the curve. If skin effect provides a shield, it should be most noticeable where the current is largest which is near the feed point.

Your suggestions of removing the meter from between the disk and removing the dielectrics from between or near the disk are good ideas. I don't see any reason why a coax or twin lead feed line could not be used. We would have to introduce a correction for the length of the feed line but that is easily done. A "someday" job/experiment.

Thanks to Ian, G3SEK, for posting this link

http://www.ifwtech.co.uk/g3sek/misc/skin.htm

You will notice that the assumption for the direction of the electrical field is that it acts parallel to the surface of the conductor, causing a current to flow parallel to the surface. The math, as well as experience of many years, indicates that the current penetrates into the surface a distance related to the frequency under these conditions.

The math solution does not deal with a condition where the the electrical field is at right angles to the surface. We then can not use the solution to predict what will happen when a voltage is applied under conditions present in the disk antenna experiment. It would be logical to use the results to make a first guess estimate of current density at distances away from the points of contact.

Hi Roy,

Yes, the resultant fields are complex. The currents actually flowing in the system should not be too hard to figure out however. The big question is whether the current in the disk flows around the edge or through the center. I think very near the center with some spreading away due to charge repulsion between charges, but the charge density would have to decrease very quickly as we moved away from the center. I don't think you agree with that.

I do not know how I could measure the current in the disk under either flow assumption. I do see how the current would cause heat in the area where the current was highest which in both cases would be near the center, but under my model would be more concentrated in the center than under your prefered model. I don't think the difference would be detectable with copper as the disk material.

I think I have a good feel for the reaction of the group to the experiment. Everyone who posted felt it was in some way faulty because it did not detect a skin effect shield factor. OK.

I should mention that the experiment I posted over a year ago (The tube capacitor experiment where I placed a metal sleeve between the inside and outside capacity plates) also did not detect any skin effect shielding. That experiment also looked for a change due to the increased path length that current would take if the skin shielding effect were present when the electrical field was at right angles to the conductor surface.

I think I will sit back and ponder the responses for a while. I will probably respond to postings less quickly, or not at all.

This has been interesting, thanks one and all for the comments.

4941. Re: Skin effect experiment with disk on antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-12 01:51:32 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D7FF324.2010902@eznec.com>
Source record: 134782

Here are two more thoughts.

1. Consider a sealed box or cable, and how good a shield it provides. Then put a slit in the box or cable, or some holes. If skin effect didn't exist, the slit or holes wouldn't make much difference -- the current would just have to detour around a bit. But you'll find that it makes a very large difference -- because it provides a path for the field and currents from the inside to get to the outside.

2. According to your theory, a shielded box made from double sided PC board material should be much more effective than one made from a solid copper sheet, because there's an insulator between the sheets which would prevent the flow of current you predict. If you suppose that there would still be flow due to capacitive coupling, you should be able to calculate the effect of the capacitive reactance you're introducing. Of course, first you've got to find some evidence of current on the outside of even the solid sheet box, but you won't be able to, if the copper is at least several skin depths thick. You could repeat your experiment with the each of the copper disks replaced by two parallel disks separated by an insulator (sealed around the periphery if you'd like) and see what a difference it makes. Fill the space between with some lossy material like water or a bunch of ferrite cores and see how much you can affect the mythical current flowing there.

There has been lot of traffic on this subject on topband reflector.
Consensus is that K6SE pennats and flags perform better than K9AY loops.

I've given my name and address (altered) time-off and again at Radio Shark and have never received any junk mail or so much as a free catalog.
So what is the whole deal with the interrogation thing? Doesn't appear that they do well by hassling their customers.
Its really stoopid that an outfit would attain notoriety by insisting on doing this nonsense with no perceivable benefit.

Of course it doesn't - because that means no current can flow along the surface.

I think you're trying to have it both ways here: on the one hand you're inquiring about the change of electrical length of the antenna, which requires that current does flow radially on the surface of your disks; but on the other hand you're suggesting that the electric field is everywhere at right-angles to the surface, which precludes current flow.

>
> Thanks.

I built one in about 15 minutes and used it for years. It's called a
"coaxial antenna".

Start with some length or another of RG-58. Slit the jacket back about
22" from the end and cut it off. Roll the braid back down over the
jacket as far as you can and "snug it" tightly on the jacket. Takes
patience until you get the drift. Cut the braid to 19" long from the
point where it starts to be rolled back around the jacket.

Cut the dielectric and center conductor to a length of 19" beyond the
point where the shield is rolled back. Lay a length of nylon twine
alongside the far end of the dielecric/conductor half of the dipole
for at least 10". Snake shrink tubing over the entire 38" long
"assembly" and heat seal it for it's entire length plus an inch on
both ends. This maneuver firmly attaches the nylon line to the end of
the antenna. Squeez a dab of any sealant into the open end of the
shrink tubing around the twine to close up the assembly.

Hang it up anywhere. From a thumbtack in the ceiling, a tree branch
outside, anyplace anywhere. Hang a PL-259 on the south end of the
RG-58 and plug it into the radio and start surfing the machines. And
it's almost a "pocket portable" antenna, major expense item being the
PL-259 connector.

The formulae indicate that the rolled-back shield should be a tad
shorter then the "radiator" based on the shield's "fat factor" but I
didn't bother with it, the thing still works just fine.

I hope nothing I wrote gave that impression. While in my limited 63 years, I know of a bunch of golfers killed by lighting, I don't know (in my personal sphere) of any hams.

The major problem with lighting protection methods is that no matter how careful you are, a direct hit is going to damage property or equipment if it hits a suspended dipole antenna.

I would not recommend that you stand in the yard holding the coax connector during a storm. You would then appear to the lighting as if you were a golfer.

Why did I know this was coming from you Richard? Of course commercial stations with engineered solutions, faraday shields, etc can operate after direct hits. A bulldozer can drive through a house with no damage to the dozer. But! can you do it with the family car?

Ham installations are not the same as commercial sites. Few hams have the luxury of the ground systems and other neat goodies common to a commercial installation.

The key word here is AMATEUR site, my advise was applicable to a ham site, please disregard for constructing a multi megawatt, sterba curtain, commercial site.

Am I totally confused? I see skin effect changing the resistance of the conductor because of the effective reduction in wire diameter, for the life of me I can't see it changing the resonant frequency.

Ergo measuring the resonant frequency, in my mind is meaningless. What am I missing?

some more :-)

> Tell you what why don't you model the K8CU LDPA in the current issue
> of QST magazine and show me where MMANA's results come any where near
> those published in the article?

I am not familiar with the design or an ARRL member (or an RSGB
member)
so I cannot comment.

But everything has its limitations.

I wish there was an option for using Greens function in MMANA, its in
my version of NEC but this is the point.

There are different ***shells*** for using the NEC engine and thats
what makes
the difference at the moment between MMANA and *my* copy of NEC WIN
PRO.

On the latter I positvly HATE the user interface and find it takes far
too
long to input a reasonable structure ***typical*** for the average
user
especially in the ham radio world.

With MMANA its as easy as using thre PAINT program that comes with
Windows.

4956. Wide-band 80 meter antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-12 13:15:55 UTC
From: Bill Ogden <ogden@us.ibm.com>
Message-ID: <3D80938B.3CBB2413@us.ibm.com>
Source record: 134796

QST (some years ago) and the second Wire Antennas book briefly discuss a wide-band 80 meter antenna, with two examples described. It consists of a "half sloper" attached to a tower, with two more wires connected directly to the tower (at a lower point) and horizontally fanned out into a "V". The half-sloper is routed down between the the legs of the V. An almost flat SWR across 75/80 meters is shown.

In one of the examples the tower is 50', the half sloper (78' long) is attached at the 45' level, and the two V legs (each 53' long) are attached at the 13' level.

1. This antenna seems too good to be true ---- absolutely flat across the whole band and with reportedly excellent results. It was originally in an April issue, and some April articles are too good to be true. Comments?

2. Little is said about how dimensions are calculated. I would like to use it on my little 40' tower (with a quad on top). I would attach the sloper at about the 30' level and the V at about 8'. Is this unreasonably small/low?

3. Has anyone tried a two-band version? It would be nice to connect a second sloper to the same feed point, but for 40 meters. Would the same V section work for both?

I realize that most of the effective radiation is from the tower and ground/radials are important. (I also realize that a dipole at 60' (or higher), or an inverted V might be a better answer, but I do not have that option.)

A recent post here described how military shipboard HF antennas work by inducing currents around the larger body of the vessel that do the actual radiating. It seems that EH antennas, which resemble paralled tank circuits more than antennas, may use the same effect. If they are just tank circuits the energy entering has to leave somewhere either in heat, magentic, ES, or EM form. It would be interesting to hear if this design can 'work' out of a faraday cage that would contain everything except its magnetic field.

I think you are complying about using a professional level program
when you prefer a more entry level. If that is the case you might want
to consider other options which will provide you with the advantages
of a NEC calculating engine. Hence I offer the following for you to
consider:

Both EZNEC and NEC-Win Plus+ have demo programs which can be
downloaded for evaluation. The URLs are"

http://www.eznec.com/index.shtml

http://www.nittany-scientific.com/

Plus there are some free programs out there too. Such as 4NEC2 and
MultiNec. The later requires Excel.

They can be download at:

4NEC2 - http://www.qsl.net/wb6tpu/swindex.html

MultiNec- http://www.qsl.net/ac6la/

Any program no matter how *nice* the user interface may be is of
little use if the results it provides are inferior.

Any of the user interfaces are a big improvement over using NEC by
itself (NEC expects to see the input on punched cards). NEC-2 source
code is free, however you need a Fortran compiler.

would be cheaper to tell the neighbors to ming there own business and leave the tower alone
just annoys me when as hams we are expected to cowar to our neighbors whims on what is pleasant to look at but yet we get no compensation on property taxes or on our morgages
so why should we worry about what they say as long as we follow the rules set forth by the FCC and any state and local building codes
our neighbors surely wouldnt do anything we ask like doing away with that bug zapper just cause its tearing up our recieve nor would they cut down a tree that is in the way of the beam path of out antennas so we could talk better
so why in the hell should a man have to dress is tower up like a tree to please a neighbor ?

Roger, W7WKB wrote:
"The resonant frequency of the antenna will be lowered proportional to the length of the longer current path."
"The addition of the disk RAISED the resonant frequency of the antenna about 0.55 MHz."

Obviously, it isn`t that simple.

Roger was attempting to add the path length of two radii to his antenna length on each side.

Problem is the radii are not in alignment with his antenna, and current flows on opposite sides of the disk are in opposite directions and are perpendicular to his antenna.

Roger`s dipole is a series resonant circuit. It seems to have an insulator in the middle and ideally would have a short circuit for resonance determination.

The resonant length of a dipole is affected by the surge impedance of the wire. It`s shorter as the surge impedance goes down, that is, when the wire gets a lot fatter. The radiation resistance drops too.

R-F resistance of an antenna is usually so low as compared with radiation resistance that in a straight wire it has little effect on resonant frequency.

I suspect that Roger was looking for a cheap way to shorten an antenna, not to disprove skin effect.

You shorten an antenna with loading coils or capacitance hats.

You prove skin effect by the absence of crosstalk in long runs of paralleled coax cables.

Best regards, Richard Harrison, KB5WZI

My use? Note the quote above, it is YOUR number not mine. Error is
error and wishing away the effects of the measurer and his devices
does not raise the level of confidence when their unfavorable biases
are denied. My use of YOUR numbers was to give you the benefit of
least perturbation - I could have easily jimmied the error to 100%
through very common consideration, but decided to let you slide at 33%
error (either is suitably egregious to kill a premise).

Again, your rhetoric does not replace the simpler test of adding
either of those two values to the standard dipole to test your
assertions.

This tracks with another comedy being played out with the debate over
"optimized" fractals. The hoot there is that the fractal champion of

2000 was offered as the best of best - none more optimal than a
supremely optimal form. It was totally eclipsed 6 times over by
random doodling. Now with the mantra of genetic algorithms,
fractalists face the enigma of putting their designs to the optimizer.
An optimized result would show the lie of their earlier assertion
(which has already been demonstrated) - OR - the lack of optimization
would show the lie of their optimization software. ;-)

What to do? What to do? Do nothing! [known as the Titanic effect,
explained below]

>
>>
>> >

>> ... to presume otherwise is another source of considerable error.
>>
>
>If a direct way is not built into Eznec, then we use the indirect way which

This is more rhetoric that moves the discussion to EZNEC which is not
the topic under consideration. Stick with the topic and observe there
is a far simpler test of your assertion that could be made in the
simple addition of a physical capacitor across the feedpoint of the
standard dipole. This appears to be a monumental task.

>
>I don't think I will do the different location experiment you suggest
>although it would be interesting to see the curve. If skin effect provides

Again, rhetoric in place of measurement - and added speculative
properties to prop up a wobbly premise that has already tumbled of
its own accord.

>
>A "someday" job/experiment.
>
>73, Roger, W7WKB

Hi Roger,

Never mind about troubling yourself with these practical
considerations, but you will still have to go to the back of the line;
behind the eh/cfa/fractal/go inventors who are demanding their share

of the pie when the technical revolution comes to a town near you. This select brotherhood is easily recognized as those who stand at the threshold, and fail to move (sort of like a first-class passenger on the Titanic waiting for an usher to show him to his lifeboat seat and the devil to those behind him - you wouldn't happen to have the keys to steerage would you?).

I have observed you need to do something different; and to that you have turned away from the prospects of this irrevocably overturning your theory (the Titanic effect); and thus we remain with the status unchanged at: failed challenge of Skin Effect (translation: your ship sank nonetheless).

The presence of slots or holes would increase the length of the current path on the shield walls. As a result, a voltage drop from inductance would add to the voltage drop from resistance, thus increasing the current flowing on the outside surface. You are aware that skin effect never stops all the current from flowing, it only reduces the current to an undetectable level for some input power level. The current would again be detectable if the power level were increased.

If skin effect shielding already separates the surfaces of the disk, then the addition of a space between two disk would would mean that the disk surfaces are now separated by skin effect and an open space effect. Trying to separate how each of the the two effects might change the resonant frequency of the antenna would complicate the experiment greatly.

Me neither. All the hams I've known that left before their "normal"
departure date, did so from inappropriate finger insertion into large
loudenboomer devices. And I've known at least 3-4 that I knew or
talked to, do that. :(Never seen one struck by lightning yet,
although I have heard of many radios being dispatched by lightning.
This is not to say I take any chances with lightning. The stuff scares
the crap out of me. I'm one of the "throw it all outside and ground
it" types. I once was out camping when the lightning got real bad. I
was so paranoid, I took my mobile antenna off the car, as it made a
good lightning rod. Lucky for me , I have a quick disconnect. MK

Boogie,
Rollo is right. Such a wide range of frequencies is simply asking too much. You truly need a dedicated (non mag mount) Hi Performance HF antenna and a separate 2m-440 antenna (mag mount OK). You see, HF is simply not a matter of "plug 'n play" like VHF can be. Think of it like this: You are compacting 130 feet of antenna down into 9 feet or less and that creates some difficulties that must be overcome. For one, the vehicle itself becomes both a "ground" of sorts AND the other 'half' of the antenna. The other problem is, due to the "scrunch-down", matching issues not present in dipoles, your efficiency is down to less than 10% even in the BEST of circum-stances, and your height above ground is compromised. So, it stands to reason that one *should* opt for the most efficient mobile HF antenna he can get. The GOOD news is that, in spite of the limitations on mobile that we can't fix, you CAN have a VERY good signal with a mobile IF you install your antenna correctly and it is, of course, highly efficient-------likely within an S-unit or two of a base!

Now. You can get pretty fair performance on 20-6 meters with those hamstick things--and, indeed, some people brag on them. But tests and "shootouts" have shown the hamsticks to come in dead LAST on 75 meters in field strength--the only thing being worse is a "tuner-whip" combo.
It takes a BIG, UGLY antenna to get maximum performance on HF, and there are no compro-mises if you are serious about HF mobile. I HAVE to be serious about my mobile because, in addition to Amateur, I am involved in CAP emergency communications, and there are times when the traffic just HAS to get thru. I often wonder what people that "brag" on hamsticks have ever compared their "good" performance to! I have a very efficient 3" screwdriver on my car, and I am confident that, assuming the same power, I would walk over a doubling station using a hamstick.

OTH, some spouses will highly object to any "ugly" antennas on the family car(s), so one must use what he can get away with! Since my wife is an "ex", I can pretty well do as I please.

We have the practical purpose idea.

Skin effect so retards a-c current that not too deeply, current phase has become reversed from that on the surface. That is, it is flowing in the opposite direction in effect.

Maybe your disk can replace a 1/4-wave stub in a collinear antenna. No, I think the magnitude may be insufficient.

Best regards, Richard Harrison, KB5WZI

How adding inductance to a circuit will increase the current is a
mystery to me, since it contradicts everything I know about circuits.
But then so does the notion that RF current flows through a conductor. I
guess if you can have one, you might as well have the other. Suspending
Ohm's law might, after all, help with the path of reasoning leading to
the elimination of skin effect.

If the hollow and solid disks have a thickness that's only a small
fraction of a wavelength (or of course if they're the same thickness,
probably not practical), you shouldn't see any difference at all between
them. Could you explain this with your view of how you think currents flow?

Mark Keith, NM5K wrote:
"I`m one of the "throw it outside and ground it" types."

That is safe in most cases. The antenna feedline, tower lighting, and monitoring circuits are paths lightning could take into a commercial station. That`s in addition to power, phone, and control circuits which anyone might have. Lightning usually prefers the flashover opportunities on the antenna end of the feedline. There are good grounds out there.

The antenna feedline, open-wire or coax, gets plenty of opportunities from arc-gaps, shields, dfirect grounds, etc to flashover before entering a commercial station.

Same for tower lighting and monitoring circuits. These get coiled up to keep r-f from bleeding off medium-wave towers. This stops the lightning too when it has a better place to go for a ground. This also works for towers which are cold or grounded, as far as lightning protection is concerned.

This isn`t really excessive for hams. It doesn`t reguire 120 radials for a lightning ground which protects, in most places.

Best regards, Richard Harrison, KB5WZI

4977. Ouch! RF in the shack

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-12 19:39:26 UTC
From: mike@mbcomps.com
Message-ID: <ea100098.0209121139.18c5c61a@posting.google.com>
Source record: 134817

Hi folks,

OK, so I just bought an HF rig, tuner, antenna, lots o' coax, and am ready to get on the air, right? Well, not quite. I have enough RF floating around that it's necessary for me to disconnect my stereo speakers when I transmit, each touch of the key toggles the VCR between record and stop, and I have to be *very* careful to not touch the metal trim on the knobs of my tuner when tuning or I get a rather nasty reminder (80m hurts the worst). I'm also afraid to let my cats anywhere near the operating post when I'm on the air (warm tubes = cat magnet).

So here's the setup. I have a G5RV up about 25 feet. It has ~30 feet of 450-ohm ladder line, which drops about 18 feet before going horizontal 5 feet, then vertically the remainder. At the end of the ladderline is what I presume to be a balun, with a connector to my coax that runs to the shack. Here, I made a coil of six turns six inches in diameter in a failed attempt to stop the RF in the shack. I did not do an exact measurement of the length of coax, but my best guess would be at least 60 feet.

In the shack, the coax goes first to my tuner (pretty obvious there), and from there a three-foot jumper to the rig. I should note that I am able to tune the antenna on 80 thru 10 with the greatest SWR being 1.2:1 on 10 (although difficult to obtain). 80m can be hit or miss, but usually tunes just fine.

I'm aware that single ground rod is pretty much useless for RF. And the distance the wire travels is certainly more than 1/4-wavelength on at least two bands. So the question is, what can I do to prevent blowing out my speakers, starting and stopping the VCR with every dit and dah, and burning the #@*! out of my fingers? I've read about using counterpoises cut 1/4-wavelength for each band and run under the carpet in the shack to act as an artificial ground is doable in situations where a long ground wire is necessary (me!). Anyone have any experience with such a setup? Any other suggestions?

Sorry for the long post, and thanks in advance for the help!

i think if i where you
i would make the ground wire as short as possible and use as heavy of wire/braid you can use and drive in 2-3 8 foot ground rods and you will want to connect the Rig and the tuner to the ground and wouldnt hunt to shorten that feedline it could be part of the problem
good luck

==========
Just changing the length beyond the trap is not allowed. It shifts the lower resonant frequency away from the specified requirement. Several other factors have to be changed as well - such as L and C.
==========

>
> But that's a different Q - the operating Q of the whole antenna, as
> measured at the feedpoint. That Q is determined by the properties of
> both the trap and the rest of the antenna.
>
==========

Wrong. They are the SAME Q. I did use the word approximately to allow for other L, C and R in the antenna.

Any multi-mesh network in a state of resonance with one principal resistive component (in our case the radiation resistance) has the same Q no-matter which mesh is tested. (The test consts of measuring the bandwidth (sharpness) of the input impedance response versus frequency.)

So you get the same Q whether it is measured adjacent to the coil or at the transmitter end of the transmission line.

==========

One of the first things you probably should do is move your antenna. If the ends of your antenna wire is directly over your roof, there is not much, except for moving the antenna wire, that will stop your problem.

4985. Stealth patio antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-12 21:41:32 UTC
From: Tom Ayers <tom@SPAMBEGONE.polyflow.com>
Message-ID: <3D810A0C.6D9584C7@nospam.qsl.net>
Source record: 134728

I am looking for some antenna advice. I am trying to get on 40 meters. I know there are commercial antennas out there, but I want to make my own.

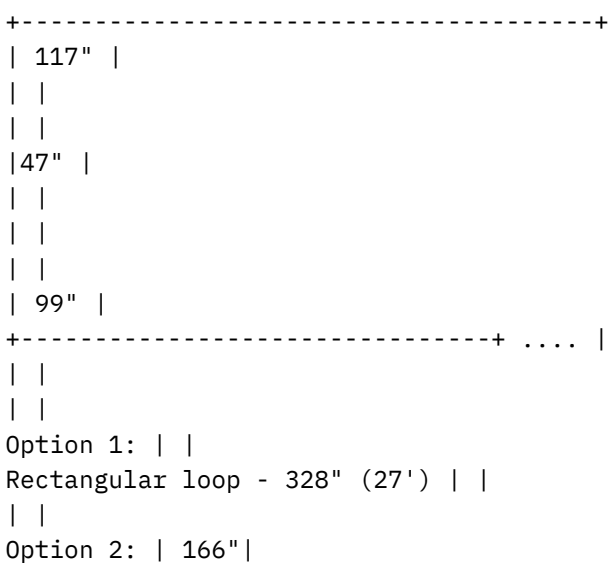
I live in a condo on the second floor of a three story building. I do not have access to the roof, or for all practical purposes, the ground. The building seems to be a faraday cage! Even the commercial broadcast AM and FM stations don't get in. Of course along with this is the usual cc&r's stating "Thou shalt not put up an antenna!" I do have a small patio however.

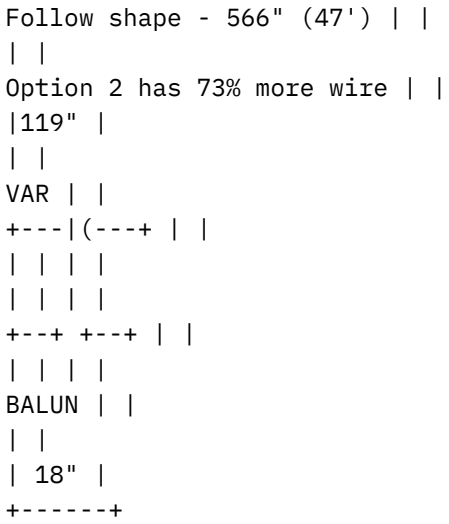
The patio is an L shape, with one side very narrow. The neighbor's patio is directly above (same size and shape), so I can put the antenna on the bottom of their patio. This is about 20 feet from ground level. I have some 24ga wire the same color as the underside of their patio, so it will be hard to see it from the ground. I will be running qrp.

I was thinking about making a loop, with a variable cap in the electrical middle. This way I could tune it to be resonant. I would feed it through a balun.

Question 1: Would I be better making the loop rectangular (Option 1). Although smaller, it is more symmetrical. The problem is that it is small. Option 2 is larger, but with only 18" in the narrow part of the patio, and the strange non-symmetrical shape, I am thinking it will be a mess.

Question 2: Ground. I am looking for the best suggestion. My choices are cold water pipe, electrical ground, counterpoise or none.





Thanks in advance,
Tom Ayers

Of course it's allowed. The whole point is that you can achieve the same resonant frequency on the lower band using a variety of combinations of L, C and outer wire length (subject of course to the requirement that L*C is constant, to maintain resonance on the higher band).

>==========
>> >Their ratio is nowhere
>> >involved, only their product.

Varying either L or C while keeping L*C constant is the same as varying L/C.

To look at it another way, on the lower band the trap appears inductive, and acts as a loading coil. You can then vary the L/C ratio to change the effective inductance at the lower frequency, and adjust the outer wire length to bring the antenna to resonance on the lower band.

When you do this, it also changes the width or Q of that resonance on the lower band. That's one very good reason to play around with the L/C ratio.

A different good reason is to position additional resonances onto higher amateur bands, e.g. to make an 80/40m trap dipole resonant on 20m and other bands too. That was W3DZZ's main objective, and that determined the L/C ratio of his 40m traps. If he'd been designing a trap dipole purely for 80 and 40, he'd probably have used a different L/C ratio to optimise the bandwidth on 80m.

>>But different values of
>> L/C can be used (while keeping the product L*C constant) - and that

I've never needed to do it in detail. But I've read the papers of the
people who did the practical experiments, including W3DZZ, G8KW and
those who came after, and can understand exactly why they found what
they did.

You're right, they are the same Q under those conditions. But we've been
talking somewhat at crossed porpoises.

You were talking about the antenna resonance on the higher band, where
the trap is antiresonant.

I've been talking mainly about the resonance on the lower band, where
the trap is not resonant but acts as a loading coil. In the latter case,
L/C ratio and length of the outer wire are both legitimate variables.

Message-ID: <t942ou8jd5t0ebprfocifqnkeib1a9vnrg@4ax.com>
Source record: 134729

I built a Hog Fence Antenna to receive ATV , and it works
quite well. I did a side by side comparison with a KLM 440-10X ATV
antenna and the receive pictures were the same.
Now I am going to silver solder something onto the back so
that iI can u- bolt it to my tower. My question is does the antenna
need to be insulated from ground or is it ok to bolt it directly to my
tower.
Also does the size of the wire mesh used to construct the
parabola have any effect on performance, would mesh smaller than the
2inch by 4 inch work better. 73

Over the years in various 'temporary' locations I have used 1/4 wave wires
to improve the RFI situation.
They do indeed help get the RF off of things. Bear in mind tho that if they
are going to be close to anyone or anything they need to be insulated. And
the ends will be very hot with RF. Keep away from burnable objects also.
Course that will only be a problem if you are running high power.

Actually its best to use FLAT strapping for a long ground. If you have some old RG8 coax around, use the shield by stripping it out and flattening it.

Also makes a convenient way to interconect your equipment.

Hi guys,

I am looking for an multiband HF vertical, what is easy and quick to
assemble and disassemble let's say in a field environment.
There are quite a few models from famous manufactures - cushcraft,
butternut, diamond, hustler etc ...
I have read reviews for all of them - some of them are better, some - just
otherwise :).
I just want to know - which of them I can use as a field (every)day antenna,
because of apartment antenna restrictions and so on ... ?
what antenna can be easily unscrewed in a couple of places to put it into a
car trunk and assemble it outdoors in 20 minutes with the same nice SWR ?
what antenna could survive after 50 of such cycles?
thanks :)

I have read more or less carefully PDFs for the most of verticals, looking
at construction details and possible problems during transportation and
disassembling.
Looks alike I don't like Butternut antennas because of huge coils - they can
be easily crumpled, and therefore change resonance frequency, I hope ...
About Outbacker: I don't believe in short antennas ... neither 8 feet stick
could work well on the bands lower than 20m ... it is my personal "old
school" opinion :)

So, I am thinking about:
Cushcraft (R6000,R8)
Hustler (4-BTV,5-BTV,6-BTV)
Hy-Gain (AV620,AV640)

Any concerns about them?

With best regards,
Alex NE7L ex.US4LNE

Are you on the second floor?

Get the antenna as far from the shack and house wiring as you can. If you suspect the house wiring is picking up the RF use a Radio Shack brute force filter on the AC line that powers your VCR.

Drop the vertical part of the G5RV vertical all the way down to reduce it picking up any induced current and sending it back the coax to your rig. Try reorienting the coax at a different angle to the antenna.

Read the stuff at the Radioworks website www.radioworks.com about "ungrounds" and long ground wires. I have a second floor shack and had all sorts of problems until I disconnected the RF ground completely and let the shack float. RF problem went away. I tried an "artificial ground" from MFJ but it did no good at all. I suspect counterpoises strung around the house might help you tune the antenna but will create more RF inside where you don't want it.

Put a Radioworks line isolator (current balun) at the rig end of the coax. A few turns of coax is probably not enough especially on 80 mtrs. Read up on coax choke baluns.

I am not a big fan of the modern G5RV. I found my 102 foot antenna worked a lot better when I just ran ladder line all the way to the window, then a big 1:1 balun from Centaur and a short length of coax to my tuner. I can tune 160-10 now with no RF in the shack even at KW power.

I thought the homebrew antenna in the April QST looked pretty nifty if you want something that breaks down into 2 foot sections easily. The others are more or less permanent.

A basic 30 foot telescoping fiberglass mast is really inexpensive. They are really fishing rod blanks. I'd use it to pull up 30 ft of wire with an L network at the base and a few 33 foot radials. An all band ground plane/ground mounted vertical. Or you can do without the tuner by implementing the "St. Louis Vertical". The problem with the commercial verticals is that thy're NOT easy to assemble and dissassemble.

> Greetings Jeroen

Aw, Boogie, you give up way too easy. Case in point - I had heard there was a 6 meter opening, and having acquired an HF rig with 6 meters on it, I punched it up onto 6 and spun the dial- while hooked to the 80/40 meter paralleled dipoles since I had no antenna anywhere close to the 6 meter band.
Lo and behold, there's a loud South American calling CQ! I punch the autotune button, and the rig finds a quick match. Well, at least it does load on 6. So I call the South American, he comes right back, we trade 599's and he goes on his way continuing the DX search.
If there's a moral it's merely that lots of things will work that you wouldn't expect, where you wouldn't expect. Including antennas. Optimization it ain't.
No, I don't plan to routinely use my 80 meter dipole on 6.

Dick

==========

Most likely RF in the shack is due to direct radiation from the antenna - almost certainly if your shack is in an upstairs bedroom.

Radiation is picked up by the transmitter ground lead, the domestic power wiring, the domestic plumbing, the transmitter power lead, the phone line, the TV downlead is a cert on 7 MHz, and any other wires in the vicinity. It is then re-radiated.

The usual unjustly accused suspect included in a round-up (as by Claude Rains in Casablanca), residual unbalance on the antenna and its feedline, can be turned loose. On the other hand, try removing the balun. Anything might happen. It probably won't make things worse.

If all else fails turn power down to 10 watts on the affected bands. ;o)

Cheers, Reg, G4FGQ.

4999. Re: Trap L/C Ratio and Bandwidth

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-13 02:41:30 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <alrj8o$5ln$2@paris.btinternet.com>
Source record: 134740

Ian, I knew all along we would eventually agree. ;o)

To tidy up -

There's an error in my introductory statement: "It is not true antenna operating Q and hence bandwidth are dependent on trap L/C ratio."

Please insert "solely" between "are" and "dependent".

The error, of course, coming from me, in conjunction with 'burning bibles' and 'human appendix' was like showing red flags to bulls.

Q is no more dependent on L/C, perhaps less, as it is on half dozen other factors. System bandwidth, the end product, is dependent on a few more. But whenever L/C is mentioned in reply to a query it is invariably implied as being the controlling factor, the point from which a design procedure begins. No mention is ever made of an optimum value or even whether higher values of the ratio are better than low values. Respondents having good memories for 'in-words' state no more than that an L/C ratio exists. There's one conclusion - the respondent hasn't the foggiest idea of what he's waffling about and contributes nothing.

He's a plagiarist who has noticed L/C mentioned at odd places in the 'literature' without any explanation which appeared to be a mysterious but somehow important quantity suitable for impressing newsgroups readers. And so propagation continues over the decades.

As Roy has pointed out, an antenna can be designed by starting with the ratio L/C. Some values are impossible. What the impossible values are are unpredicatable. The eventual computed overall length will be any anybody's guess.

By starting with antenna dimensions the antenna user can be sure it will fit into his back yard.

Program TRAPDIP begins by entering antenna overall length. L/C ratio can please itself.

==========

PS. The only information I have just found on the subject (I didn't spend much time searching) in the 18th Edition of the ARRL Antenna Book, page 7-10, was "Unfortunately, high (coil) Q restricts the antenna bandwidth because the traps provide maximum isolation only at trap resonance."

The first part of this sentence is incorrect. It is not the loss resistance of the coil which controls antenna operating bandwidth. With a good coil, antenna Q and bandwidth is controlled by antenna radiation resistance which

is effectively in shunt with coil reactance. Radiation resistance (at the end of a dipole) is of the order of 50 or 100 times smaller than the equivalent shunt resistance due to coil loss and so completely swamps it.

The article goes on to describe the coaxial trap which it is stated has a high impedance and low (coil) Q (low shunt coil resistance) and "effectively overcomes the bandwidth problem". It did not occur to the author and editor that it achieves this objective by using the coil as a minor dummy load. Old wives ? The same effect can be achieved by winding an ordinary coil with more turns of thin wire and with a small C, which incidentally has a high L/C ratio. ;o)

Alex

For three years straight Ive been doing Jamboree on the Air with the Boyscouts.. Ive been using my base station vertical.. Its a Gap Titan DX.. With no ground radiials necessary it is really nice to setup and operatate. the vertical folds over in two peices and fits in the back of a full sized pickup truck. I made a pvc base for it and secure the ant with nylon line and tent stakes. It works very well for portable operation. SWR is very good and I do not need an antenna tuner. However this is not a small antenna but I have not had any probs.

>that it achieves this objective by using the coil as a minor dummy load.
>Old wives ?

Seems like that portion of the handbook needs to be revisited.

'Mature' handbooks like the ARRL series gradually get refined over the
years, but the process is being hugely speeded up by Internet
discussions.

After looking at the photo, i might suggest that you may want to consider a true mini quad antenna.

Take a look at our page at www.degendesigns.com and see if this might solve your problems.

That`s optimistic!

Art Unwin, a contributor to this group complains that change in the ARRL Antenna Book, seems to be an occassional repackaging of the same old stuff.

Best regards, Richard Harrison, KB5WZI

I agree with you about neighbors and have told a few to kiss off over
the years. I also understand some people are not into confrontation.
This guy, with all the patriotic fervor he can muster, could put up a
lighted flag pole that would work very well on a lot of the bands.
The small trench he puts in for the low voltage lighting would also
hold the coax pipe. He could even get away with running a thin wire
to another structure for an inverted L. There are lots of ideas out
there for hidden antennas that will do the job for him.

BTW, if covenants are the problem, get ahold of your elected federal
officials and tell them if they want your vote to extend and strnghten
PRB1 to cover everything and put some damn teeth into it!

Hi Tom,

If this is seriously true, then you have a massive conductive
structure that is going to overwhelm any nearby antenna.

OR

Find a point of the physical structure that exposes a metallic
connection (or simply indicates a convenient point to this cage).
Connect (or link) a matching network (gamma feed, or loop excitation)
to this point and drive the building! Be the first on your block to
work the world from inside your antenna.

No, it's true. Before the Internet, the correction process consisted of writing letters to the editor, who might or might not have had time to think about it.

Today, any contentious or weak points are likely to get thrashed out right here. Many people contribute to these discussions who would never have taken the time to compose a letter to the editor, and the problem gets the benefit of several different viewpoints from all around the world.

We've all seen how years-old antenna problems can be sorted-out here in a single day, and similar things are happening through other amateur radio newsgroups, mailing lists and private e-mail. Groups of people interested specific topics are getting together from all over the world, and pushing forward faster than ever before.

We're witnessing something completely new here.

And at the end of it, if anyone still feels strongly enough, the ARRL handbook editors are only an e-mail away.

>Art Unwin, a contributor to this group complains that change in the ARRL
>Antenna Book, seems to be an occassional repackaging of the same old
>stuff.
>
This has already been discussed at length. As has already been pointed out, the handbooks are a distillation of present knowledge, so you should expect only a gradual evolution. It isn't realistic to expect everything to change radically from one edition to the next.

It's also unrealistic to expect any publication to come out perfect and completely beyond criticism.... especially with this NG looking at it!

What you *can* expect - and are actually getting - is progressive improvement and updating.

I have found that the system for correcting the ARRL handbooks is very accessible and responsive, if anyone cares to use it... rather than just talking about it.

People that tell other people to get a life, probably need one themselves...

Do you walk up to a group of people in a bar and tell them to get a life
because they talk about something your not interested in? Then why would you
do it here?

Tom,
None of your options sound good, and I think you're
pretty well out of luck. I think your best bet would
be a dipole made from two mobile antennas, set it out
to operate and bring it in when you're finished. I'm
sure there might be some way of stringing a 'Rube
Goldberg" antenna in your available space, I'm just not
too sure it would be worth the effort...

hey dan
your right on all counts there are many differnt hidden antennas and such
but i assumed he had a tower up and the neighors where bitching and to that i tell
them to kiss off
hell you could even do a long wire or a loop running around the eaves of the house if
the neighbors ask tell them its a messanger line for haning Xmas lights from
there are a couple of commercial antennas that are stealthy
one is the ventenna and the other is a weather vane antenna both are for VHF/UHF and
go on the roof and no one knows what it is

but in this world of ours and the amount of community service hams do i think its
appalling that we have to jump thru such hoops to enjoy our hobby and to stay
perpared for emergancies that the community atlarge cant just leave us alone to do
what we wish
now i understand that if you are stupid enough to buy a house in a deed restricted
area and you knowingly sign these restrictions then you have to work around them
but when the ones of us who dont live in those types of areas and get dictated to by
neighbors i think its awful

okay i am off my soap box
happy hamming

5023. Icom AT-120 & Dipole Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-13 17:47:22 UTC
From: David <dadow@PinaculoConsulting.com>
Message-ID: <Kwpg9.11614$S32.833205@news2.west.cox.net>
Source record: 134762

I have returned from installing an Marine SSB and I was given an AT-120 tuner as a result. I am planning on taking my General Exam at the end of the month and I am trying to design my rig. Presently, I have an IC-736 (HF/6M) rig and I also have a 40-20-15-10 Alpha-Delta dipole installed that I have been using for receiving.

My question is:

Can I configure the AT-120 Automatic Antenna Tuner to work with the Dipole? If so, would I connect one end of the dipole to the antenna output from the AT-120 and the other end to ground connection? Do I need another ground counterpoise?

I have installed three Marine SSBs on boats and it is a whole lot easier because of the salt water ground and random wire antenna. This land based stuff is a whole lot different. Would I be better off running a random wire?

Thanks for the help.

Dave KD5OEQ

Public committee meetings? Are you joking ?

Newsgroup arguments ending with mudslinging have the effect of further obscuring the correct 'answers'.

From the many different heated 'answers' how is a handbook editor to choose between them?

Take the average?

A majority vote?

A majority vote on popular misconceptions would result in present popular ideas being set, unchanged, in the handbook's annals for evermore.

Or should bullies who shout loudest provide the correct answers?

Consider the consequences of NO correct answer in the bunch.

There's no alternatve to technical editors taking sole responsibility !

Reg, G4FGQ, RSGB member.

That choke is too small a value to be much good for 80m. But even if
you made the choke larger to suit 80m better, I'm sorta doubtful it
would fully cure the problem.
>

> but usually tunes just fine.

As many others said, make sure the antenna isn't right over your
shack. That can cause problems sometimes even if the setup is working
ok. Myself, I'm with Reg on this one. I would dump the coax
altogether, and run 450 line the whole way from the antenna feedpoint
to the tuner. That may not totally cure the problem, but I wouldn't be
surprised if it helped a bit. There is no decent reason to use coax at
all, if you are using a tuner. I find a setup like that fairly silly
myself. "Not blaming you though"..

Grounding may or may not help, but remember that the real problem most
likely is excess common mode currents on the feeder assuming your
antenna is not right over your head. Grounding to cure RF in the shack
problems is a bandaid. I don't recommend going that route. You want to
cure the *real* problem. The way I see it, the only thing grounding

might help, is to keep you from getting bit when you touch your tuner. I doubt it will help at all with the VCR, etc. Also, VCR's are notorious for RF problems. You may not be able to cure that even with all ok elsewhere. Those decks, and the heads, etc are very sensitive to rf, and most are not shielded well at all. I have a pretty much rf free shack, but I still whack out my VCR in many cases, just from the normal field strength of the antenna itself. If all fails, you may have to get the antenna farther away, and you might want to consider coax feed with a good balun at the antenna if all else fails. Of course, this would limit you to pretty much a single band antenna though. You could parallel other dipole legs though. I'd try straight 450 line to what you have and see if it helps. Also, it's possible you might be better off with a normal 120-130 ft 80m dipole instead of the G5RV if you have room. MK

If I remember correctly, W8JI had good results using short phased
receiving verticals. He also has beverages, and I think I remember him
saying the verticals were just as good in many cases. I may try that
route myself, as I have no room for long antennas. I know he hears
stuff that doesn't exist on my transmit antennas. "dipoles, Inv L,

Hello everyone. I am going to buy the Yaesu FT-100D Receiver. There are two antenna inputs for it. One for 2 metre and 70cm, and the other for HF and 6 metre. Since I only have my basic ticket here in Canada, I can operate the 2 metre and 70cm, and also the 6 metre band. I already have a 2 metre J-Pole that I'm using now, so I could get by with that. But my question is, is there anything home brew I could put on the other antenna input to allow me to work 6 metre, and also LISTEN to other HF bands?

Any input greatly appreciated.

Hi, all concerned:

Asplundh recently plundered all if not most of the tree branches capable of brushing the power-line primaries in the neighborhood surrounding my suburban location. You ought to hear the crews' war stories re the tree-hugger grieving and outright physical interference. But, that's a subject for a flamefest elsewhere.

Now, it's comparatively quiet here. H-f and 160M are useable again during sap-up as well as sap-down. Deo gratias. I also thanked the lads for giving me back the use of h-f. :o)))

I hear the neighbor's electric fence (around his 5-horse-pen) very well on h-f now; it's about 900 ft away :o(Haven't introduced myself to him yet, and want to do my homework first. I have met the horses: they get out and wander around once in a while. That's okay by me.

The noise-blanker is a good interim fix, and I can reduce but not null the noise by antenna orientation, but what can I do to help him fix the *TICK* *TICK* *TICK* I can see on my 'scope and Millivac broadband v-m if I connect either to an antenna?

TIA & 73,

Dave, N3HE

Hi Dennis,
If I remember seeing this guys original post, he was just trying to
hide the comet. Which is an almost impossible feat to accomplish.

I have been in several situations where a few neighbors tried to ruin
it for me. At first I bent over backward to appease them (Young and
naive). Then I realized the neighbors at that location, were hearing
the getto garbage off 11 meters and not me. A few I helped out with
filtering and such. They were very grateful and were my biggest
backers. A few I told to come on over and talk to me without a fence
or a phone in the way;<}. They never did.

Now, if someone comes to the door with a rfi complaint, I commiserate
with them on how cheap their electronic equipment is built even though
the manufacturer charges an arm and a leg for it. I go into a spiel
on how it would cost less than $5.00 per component to construct it so
it would not receive things it was not designed to receive. If they
have the manual with them or handy I ask to see it, look through it
very carefully and then say, yup, I was right your component is doing
something it should not be doing. Then I quickly tell them to call

the manufacturer or retailer and complain because they got a defective or deficient unit and demand it be brought up rfi proof operation.

I have been here 18 years and have not had a complaint, one neighbor kid did say he heard me over the phone once in a while :o}

At least twice in the past year or so, someone on this newsgroup has pointed out an error or misleading text in the ARRL Antenna Book. I've passed the information along to the editor, and I'm sure the corrections will be in the next edition. Dean is completely capable of making a good determination of whether proposed corrections are valid or not and, in those rare instances where he's not certain or where there are possibly valid but competing points of view, he's asked advice from the ARRL Technical Advisors. That's one of the TA's functions.

The newsgroups do help, if the information is channeled to where it can do some good. The tecnical editor does take total responsibility for changes and what they contain. But he can't, and doesn't, operate in a vacuum.

Fred,
I think if you had grounded the shield of the coax where it enters the
house the lightning would likely have been happier to go to ground
right there. Yes, the approximately #12 wire might vaporize but the
huge currents in the house are not what we want.
If I understand correctly, to paraphrase (I think it was the QST
article) the lightning decides to strike, picks out your dipole, (not
because it was really the best target), and THEN all those billions
of electrons get into a traffic jam trying to get into the ground.
The hams job is to make the path easy to find, and big enough for them
to all fit into, and to avoid having to deal with the fire department
and the insurance company!

Roy describes a sound process. The Antenna Handbook has become the "Bible" of practical antenna building. If errors are contained within after so many years of publication, then they are probably very subtle.

If an error is found, it may be that not everyone will recognize it as an error. In that case, there may be a series of handbooks where an editor's note or a sidebar explaining an alternate interpretation may be necessary. Obviously, the alternate viewpoint must gain some level of creditability before any editor could risk his own creditability by including it in his work.

Source record: 134676

This is a great discussion we have going here. Unfortunately I have found this discuusion in three places in this newsgroup. Maybe someone changed the title ever so slightly ??

Anyway, as for me, I am right in the middle of implementing my grounding plan as per the QST article and my consultation with Ron Block the author. So far I have one radial in with its 4 ground rods. 7 more to go. Then I start work on the entrance to the house. At least the weather is perfect for digging now in NJ. 70 degrees and low humidity. When finished I estimate to have at least 40 ground rods and 750 ft of copper wire in the ground.

5038. G5RV Slingshot technique

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-14 00:12:13 UTC
From: Wayne Sellin <sellinwg@starpower.net>
Message-ID: <altv1i$rn8$1@bob.news.rcn.net>
Source record: 134678

I am having trouble with the slingshot. The 4 oz. weight get hung up in the web. It seems to work better with smaller 2 oz weights but then they do not have the mass to pull the fishing line. Also the round weights do better than the teardrop. I cannot find the colored fishing line here. The Whackos probably think it has a bad effect on the environment.
I do by the way have one of the trees set up with three lines. One line is a loop backup in case one of the lines break. The second line holds the pulley high in the tree. The third line is through the pulley to the antenna. Just as described in Radio Works. com except I added the backup line.
Thank you
Wayne

5039. Re: G5RV Slingshot technique

Message-ID: <3D829DF1.8020406@eznec.com>
Source record: 134679

I've been using a slingshot and weights for many, many years for portable operation. Here's the system I've evolved after a lot of trial and error:

1. I use a 2-1/2 or 3 oz weight, not less. Otherwise it sometimes won't fall through the branches. (Trees here are conifers of several varieties, some pretty dense.)
2. I use 8 pound line, which has the strength to get the twine back over the treetop, and can handle minor snags.
3. I really like the fluorescent line -- it's much easier to spot. But regular monofilament is ok.
4. I use only the teardrop shaped weights (narrow end where the line attaches). They're a little harder to get positioned in the slingshot correctly, but they don't snag like a round or pyramidal one (with the fat end at the line attachment). In your back yard, try dragging a round weight through even very sparse brush, then try it again with a teardrop shaped one, and you'll see what I mean.
5. I spray paint my weights with day-glo paint, so I can see them when they don't fall all the way through the tree.

With this system I can shoot a weight up about 100 feet.

I don't use this method for permanent installations, since the twine cuts into the tree pretty rapidly and seizes. Then there's no way to get it down. I've heard of people using very heavy monofilament line (100 pound test or so) and being able to get it down after some time. But this might also depend on the kind of tree -- conifers have fairly soft wood and sticky sap, so they might seize worse than hardwoods.

well you could build a 6 meter dipole that would be cheap enough ans easy
enough to build and would allow you limited recieve on HF
what you should do if get yourself that cushcraft triband yagi
its 3 elements on 6 meters and 5 elements on 2 meters and 440
so you would be able to atleast have some performance and gain there
the antenna is around $150USD i think
good luck

5041. Need Hints on tuning fan dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-14 03:09:28 UTC
From: Steve KC8PBO <skaatznospam@ameritech.net>
Message-ID: <ILxg9.8346$yt3.4380777@newssrv26.news.prodigy.com>
Source record: 134683

Need hints/advice on tuning my 3 wire multiband dipole. I can tune SWR dips near the design frequencies (center of the bands), but the SWR ranges from 2:1 to 3:1 for the bands of interest. I'm hoping to do better than that.

Here's the setup: It's center fed with coax (open wire isn't feasible for this installation). 1:1 choke balun at the feedpoint. The top (longest) wire is 80' with a loading coil at the 33 ft point on each leg (it's a converted Alpha Delta SWL antenna), so the coil is in the 80M leg and the 40M has a ~33 ft leg. The next one down is cut for 20M, & the bottom wire is cut for 10M. About every 5' there are plastic spreaders placed to separate the wires about 4".

Both ends are ~30 ft up, and the center point is at 35ft.

I suspect part of the problem is that the installation is asymmetrical: 1 side of the dipole is about 12 ft above the roof of the house, & the other side is pretty much in the clear. This is the only way I can use the lot for a decent length dipole.

I've tried adjusting the legs one side at a time, starting with the longest wire 1st and iterating to minimize interaction.also lower and raising the ends to change the included angle like an inverted VEE...but no SWR less than 2:1.

One weird thing is that the SWR decreases when I lower the center insulator about 6' from the top of the 12 mast?!?!

Any hints on how to balance this thing out or lower the SWR?

Thanks

There was an obvious error that continued in the ARRL publications
for many years. It was in my 1976 ARRL Handbook in chart form and
in my 1993 ARRL Handbook in graph form. For 450 ohm ladder-line,
the attenuation at 14MHz was given as 0.09dB/100' and the attenuation
at 21MHz was given as 0.13dB/100'. These values were reproduced on
the graph in the later editions. It was corrected by the time the
2000 Handbook was published.

Shoot with 8-10 lb fishing line. Pull back through a medium weight nylon line (like bricklayer's twine used to establish level) and do your final installation with heavy nylon weed whacker line. It is really tough and available in large rolls for cheap. it is the devil to tie in a knot but super strong and won't disintegrate in the weather.

5047. Disposable Mobile HF Antenna??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-14 04:47:09 UTC
From: n5kzw@arrl.net
Message-ID: <3d82bd28.3695072@news.ev1.net>
Source record: 134687

I give up! So far, I've sheared off a Hustler, two types of bug catchers, and now, a Hamstick. (I didn't shear off the screwdriver, but it doesn't work any more.)

Apparently, my reckless (unfortunately, not wreckless) driving style and the trees on the ranch are just not compatible with HF antennae. I'm thinking of coming up with some sort of Hamstick-like antenna wound on a broomstick, with top and bottom connections made of copper pipe sections.

Question, the 17-meter Hamstick has a section that is closely wound. Is this some sort of phasing coil? Can I just wind enough 12-ga. wire on a broomstick to get to 1/4 wave (with the whip) and slap a matching circuit at the base, or do I need to duplicate the close-wound section that shows up on the Hamstick?

Regards,
Ed Bailen

Most of the interaction may come from the antennas being in the same plane. Most single fed multidipoles are set 90 degrees apart to minimize this. You might try adjusting the wire lengths from the shortest to the longest. When you adjust multiband verticals, you start with 10m and then 15m, etc.

Also, if the rig has a built in tuner, it should handle anything under 3:1. The question is Are you making contacts?

Check out the "SuperAntenna MP-1". I've tried it out on 20m at QRP to 100w
and it seems to work well. You'd need an antenna analyzer to set it up.

I put a short review that I did for the local radio club onto e-ham.net.

Ed,
If you want to duplicate the hamstick, you have to
wind your new antenna like a hamstick. The closely
wound section of the 17 meter hamstick is the loading
coil, there is no 'phasing' coil on any hamstick.

How did you kill a hamstick? That would take a mighty blow unless you
are just talking about the whip attachment point on the top of the
stick.
>
> Apparently, my reckless (unfortunately, not wreckless) driving style

> pipe sections.

I don't see how that would be better than a hamstick. It would be so
rigid it would just snap in half if you hit a tree. What you want to
do is make the antenna very flexible. So you want to use a longer
stinger which is nearly indestructable. So if you run 17m, use a short
10m stick, with a longer stinger on it. You can attach the stinger to
the top of the stick with very small hose clamps. I use two of them,
and I've never knocked a whip off unless I didn't tighten them tight
enough. You could use three if you want to be extra safe. Also the 10m
stick on 17m, will outperform the regular 17m stick, unless they
design it to use a long stinger. You only need about 1.5 - 2 ft or so
of stinger to put a 10m stick on 17m.
>
> Question, the 17-meter Hamstick has a section that is closely wound.
> Is this some sort of phasing coil?

Thats the loading coil if you are talking at the top of the stick.
They wind closer at the top to improve current distribution. If you
see a small coil at the bottom of a few turns, thats a built in
matching coil.

Can I just wind enough 12-ga. wire
> on a broomstick to get to 1/4 wave (with the whip) and slap a matching
> circuit at the base, or do I need to duplicate the close-wound section
> that shows up on the Hamstick?

You have better current distribution with the coil wound near the top.
With a stinger on top, you have a center loaded antenna with a narrow
coil. But you can wind them the same pitch all the way. But I think
putting the coil at the top is better. I've been using modified sticks
for over ten years, and have hit many trees, but I've never broke an
antenna yet. I'm still using my original "80-10" version that I made

years ago. I use a long enough stinger that it just slaps off anything I hit. The stick itself is fairly flexible too , to a point. I've had mine bowed nearly 90 degrees in drive thoughs and didn't break. I use a regular hustler quick disconnect, and it's strong enough to take any force from a hamstick. I've never had it fail once. Cheaper rinky dink quick connects I've seen will fail fast. They just can't handle the forces. MK

5054. Delta loop feedpoint question ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-14 10:50:42 UTC
From: dxer@aol.com

Source record: 134694

I am thinking of putting up a 20 meter delta loop. I want the polorization to be horizontal. I will put it with the apex up.
I am thinking of feeding it at the apex. From what I have read this will lower the angle of radiation some over feeding at the middle of the base/bottom. And of course this will rasie the feedpoint much higer above ground.
My question; With feeding it at the apex, the coax will be coming straight down through the middle of the delta. Will the coax interfere with the operation of the delta at all this way ?
Tnx

You are probably coupling with some house wiring. 2:1 or even 3:1 SWR
is fine as far as line loss is concerned. So all you have to do is
make your radio happy. I'd just stick a little tuner on it and go.
That would be easier than trying to fine tune the legs. The only time
I've ever seen a problem like that was near other metal. I once made
one over a tin mobile home for a friend one time, and we had a heck of
time trying to get a decent match. The metal of the mobile home, and
not being able to get high above it, was the problem. MK

> concerned.

It's gone straight to ground via my mast here. It acts as a lightning
rod. The antenna and coaxes seem to just float for the most part.
I've seen no damage to them , or evidence that they were a conductor
for any decent amount of energy. Or at least enough to damage the coax
anyway. And they are taped to the mast. But they don't lead to the tip
of the mast. The breaker box, lead in, phone lines, cable tv, etc,
were only a few feet away. No damage noticed to anything in the house.
I'm only 15 ft from the strike point myself if I sit in this chair. I
was the first time.. I was 3 more ft across the room, the 2nd...
>
> This isn`t really excessive for hams. It doesn`t reguire 120 radials for
> a lightning ground which protects, in most places.

I don't have any real radials as a lightning ground. Only the wire
that connects my set of ground rods together under ground. My ground
rods are only 3-4 ft long on average. Just scrap pieces of copper tube
that I find. I've pounded a few into the ground at the base of the
mast. They are all wired together, and that grounds the mast. I'm also
tied to the cold water pipe which is 2 ft from the base of the mast.
So far, it seems to be good enough. But we do have pretty conductive
soil here. I also have a ground at the entrance to the shack, and it's
connected to the ground at the mast. The mast is the center of the
"star" in my case. The ground at the shack is just to ground out the
coaxes to route any extra energy to ground. I do not connect my shack
to the outside grounds at all. MK

First, help him round up the horses the next time they get out.

Then a couple things to try are to check for grass or brush that is rubbing it, much like the utility company did for the power lines(tell him that they drain the charge and reduce the effectiveness of the fence). also checking and replacing or cleaning dirty insulators may help some. also make sure it is connected to a ground rod close to the charger and not through the wiring.

the best you could hope for would be for him to turn it off when the horses are in their stalls, tell him its a power saving for him.

A coax fed 40m dipole also presents a decent load on 6m for me. That would make it 7 half-waves on 6m (7*7.2=50.4 mhz). I have used HF dipoles on 6m many times and find they work remarkably well. Of course, you have lots of lobes and nulls, but that is the price of convenience. I'm using mine on an FT-847 and VSWR < 1.5:1 at 50.125 and under 2.5:1 over most of the 6m band. It was a nice find. During E-season it works extremely well, (as will any antenna that presents a decent load to the transmitter) and I worked plenty of DX with my 90' long extended double zepp for 20m on 6m. (This antenna was fed with shielded balanced line and a tuner, so don't try using it without a tuner, use the 40m dipole example below)

Having the 40m dipole will allow excellent transmitting and listening on 40m, reasonable transmitting and listening on15m as well as surprising transmit and receive performance on 6m. To listen on the other bands, you could tie the center conductor and shield together at the coax connector with a clip lead, and listen with it as a random length wire. For listening purposes it will be quite adequate.

Don't expect it work well in its "normal" dipole configuration on 80m, or on any band for which it is even harmonic resonant.
Example: 20m, 10m. I haven't bothered to check it on the WARC bands, so just keep in mind the even harmonic prohibition, and on those bands use it with the center conductor and shield tied together fed as a random length wire.

40 meter coax fed dipole for multi-band use without tuner: (approximately 33' each side of center)
(with tuner you can transmit with it in the random wire configuration)

80m: random wire, a bit undersized (short center conductor and shield)
40m: resonant half-wave dipole (no tuner required, feed as normal dipole)
30m: random wire, but try it both ways
20m: same as 80m
15m: resonant 3 half-wave dipole (no tuner required, feed as normal dipole)
12m: random wire, but try it both ways
10m: random wire, nice length, will have gain in some directions, nulls in others)
6m: resonant 7 half-wave dipole (no tuner required, will have pronounced gain and nulls)

hope this helps you out. 73

The coil is a loading coil which neutralizes the capacitive reactance
associated with a short antenna. Instead of a broomstick, I would
suggest 1.25" fiberglass pipe. That's what I use - tough stuff.

I guess I agree about being sick of seeing the tripe about RS employees. I used to work for RS... not in a store. Some are incompetent. Some are quite good. But, in either case, I'd hate to deal with some of the people they encounter every day. Today, it's a whole new set of management since I was there, and they well may be REQUIRED to push phones, etc.

Fortunately for those who are tired of this thread, Outlook Express --and probably the rest of the browsers-- allow us to create a filter so we will never again see a message whose subject contains "RS employees." (That also means I won't see replies to this post.) I've always found that to be the better solution than criticizing the folks who enjoy the thread in question.

Kenneth, K4XL wrote:
"I am particularly interested in the 2-loop KDAY."

A search using the MSN search engine and "K9AY" produced 594 responses.

I chose a response titled "HCDX" which compared a "Wellbrook K9AY" with Beverage antennas on a farm in Northern Jutland Denmark.

"The antenna simply requires up to two 25m wire loops. A single 8m vertical support is required such as a tree."

"My main interest is MW from Canada and USA, and there the K9AY was inferior compared with the Beverage-antennas. In about 80% of all cases the Beverage had a louder signal with absolutely no background noise. In 10% of the cases both were on a par and the rest the K9AY had the edge."

There is much more to the comparison which you can find on the web. I often used a Beverage in Portugal to listen to WCBS and WWL after midnight local time when I lived there. Reception was good.

In limited space, a phased vertical array receives with the same pattern as it transmits. These were used by the West to continuously monitor stations in the East during the Cold War. Loops with air cores and ferrite cores were also used because they could be quickly be redirected for occassonal monitoring and require less space. I visited some sites.

Source record: 134704

I don't think it would hut anything, I made a delta loop for 17 meters and
it worked great.

I fed mine at the apex, the feed point height ws around 40 feet, I also
tilted the delta away from the tower at about a 30 deg. angle.

FYI, the feed point inpedence of the loop is around 100 ohms so you will
need to fabricate a 1/4 wave series section matching stub type transformer,
this can be done by using a length of 75 ohm coax cut to the correct length.

I can't find my antenna book so I can't provide you the formula, maybe
someone will post it up.

have fun with your loop

The fields tend to cancel at the coax if the installation is perfectly symmetrical. But consider this: The current at the feedpoint is maximum and is approximately the same as the current close to the ground opposite the feedpoint (in a one-wavelength delta loop). So what advantage would there be to feeding it at the top instead of at the bottom?

I modeled a 40m delta loop like the one you describe. The gain is actually slightly higher when feeding it at the bottom than at the apex. Save some coax and feed it at the bottom. You can model your antenna with the free demo version of EZNEC available from http://www.eznec.com

5066. recommended preamp?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-14 18:30:10 UTC
From: AJ Sanderson <ajsand@nospam.com>
Message-ID: <am0u6l$h5h$1@nntp9.atl.mindspring.net>
Source record: 134623
Cross-posted to: alt.ham-radio.mods,rec.radio.amateur.antenna,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I just inserted an in-line HF antenna device that reduces signal level by 8-12 dB. I'd like to compensate for this by using an antenna preamp for the HF bands. I'd like to homebrew the preamp. I've been looking at several designs but can't decide. I'd appreciate some recommendations and/or pointers to some sights with good preamps. The receiver (transceiver) used will be an Icom 718.

Thanks, in advance, for any suggestions.

AJ

5067. Copper Wire Stretching?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-14 18:58:12 UTC
From: Dan Richardson <k6mhe@mendolink.com>
Message-ID: <ik17oucpppoedo494e1adcq6h7mctk63mk@4ax.com>
Source record: 134707

I am wondering if anyone has information on the amount of stretch involved in typical wire antennas using copper wire. Proponents of copper clad steel wire seem to feel that copper wire's (hard or soft) stretching is an important issue. Of course tension and time would play a factor but for antennas such as a dipole are usually under less than 50 Lbs. pull. (Mine are less than 30 Lbs.) So I am wondering just how much increase in length in percentages are we talking about?

Hi Danny,

If you have any dumbbells or free weights in the back of the closet,
then you could do your own dead-weight test with a sample length
suspending that weight from a hook in the rafters (the longer the
wire, the easier to measure). Add the weights (or tension) slowly so
that the distortion/stretch is not a product of impulse.

Cecil A. Moore has already answered DXer`s feed option question.

DXer may want to examine the horizontally polarized delta loop`s other characteristics. It can work well if high enough. It can also easily be a cloud warmer if too low. ON4UN`s "Low-Band DXing" has good information on page 10-7 and surrounding pages.

Stretch is complicated by temperature, wind, ice loading, etc. Short answer is to use Copperweld if there may be a problem.

For appreciation of factors see: Edmund A. Laport, "Radio Antenna Engineering"---Wire Stringing---beginning on page 466. Ed says:
S = W(Lsquared) / 8T.
S = sag in feet
W = wire span weight
L = feet of wire in span
T = tension in pounds

Tensile strengths can`t be exceeded and are given in handbooks and catalogs.

Best regards, Richard Harrison, KB5WZI

Rick:

Anone with his antenna coax grounded outside the shack with a #12 wire is deluding himself if he thinks he has any serious protection. The liklihood of the path to ground being more attractive through his outside ground than the house wiring ground is slim to none. If he never suffers serious damage he can count himself very lucky.

If lightning does strike and vaporize his #12 wire it will also raise the voltage on the coax braid way, way above any level that can be withstood. At that point, his gear and the rest of the house gets charged up really well. I sure hope he's not sitting in the shack blithely assuming he's protected.

Dick

And if you are using open wire line and a tuner, it won't make any difference because you can tune the whole system to resonance. If you are using a resonant dipole, then the length does become a factor, and the increased length from stretch will tend to lower the resonant frequency of the antenna.

73,

Wayne, W1KI

Hi Richard,

This seems to be a fairly circular specification. That is, it asks
for tension to find sag, and tension is exquisitely related to sag.
In other words, which came first, the chicken or the egg?

More to the point, you have to measure the tension in service, and if
you are already there, you may as well measure the sag directly (who
needs a formula at that point?). - OR - If you calculate the tension,
it is on the basis of a known weight and a known sag (you already have
the answer then too).

For instance, a hanging wire offers a mathematical form known as a
curve of constant acceleration (tension) or catenary. For small sags,
this curve can be approximated as a straight line out to the half way
point (where the weight is presumed to be for calculation), with a
mirror line back up to the opposite suspension point. If the weight
of that wire were 10# and that line was depressed below the horizon by
1ï¿½ then the tension would be 573#. Change that by only 4ï¿½ more (to
5ï¿½) and the tension plummets by more than 80% to 114#. Add another 5ï¿½
and the tension plummets by near half to 57# or roughly 10% of the 1ï¿½
sag tension we started with. What price 9ï¿½?

What the math reveals is that with an appreciable sag, the tension to
sag it further becomes progressively weaker with the sag - self
limiting - otherwise ALL wire antennas would be on the ground by now.
If you start out with a modest sag (and 10ï¿½ certainly qualifies) in
the first place you stand a chance of no further sag. Contrary-wise,
if you have a personality type that likes to cinch up such matters,
you will have a lifetime occupation in the pursuit of your favorite
activity (limited only by your economic means to purchase anaconda
copper).

5076. Re: Mixed blessing

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-15 00:27:42 UTC
From: Ed Juge/NM <ed@juge.org>
Message-ID: <3d83d4a7.0@oracle.zianet.com>
Source record: 134716

I had one of those fences next door to me. My neighbor installed it to keep deer, bear and such out of the flowers in his back yard. It was 20db over S9, on one second, off one second, 24/7.

I got the manufacturer's info from the controller and called them. I figured they would blow me off. Instead, the guy was quite helpful and gave me a laundry list of things to check and/or fix. It COMPLETELY killed the problem.

First off, they told me when a fence is producing the kind of RFI I had found (copyable at 1/2-1 mile) the 4000 volts that was supposed to be on the fence was probably was down to around 600 volts and quite ineffective. NOTE: This is an especially good argument to present to the fence owner. I did so and offered to try to fix it for my neighbor. He was only too happy to grant permission.

Their suggestions were...

Make sure the ground is short and heavy gauge wire.

The wire from the controller to the fence MUST be made for this service. It must have at least 6000 volt insulation, not 300 or 400 volts like AC zip cord.

ALL connections on the fence must be made with electric fence wire clamps. Especially look for splices. It is much better if all wire is the same material... no copper twisted to aluminum, etc.

Remove any grass or bushes growing into the bottom wires.

Be sure you don't have any of the wires touching trees... that's common especially with insulators made to nail into tree trunks.

You can probably trace the noise source by using a portable AM radio. If you're lucky enough to catch it when the noise has stopped, walk the fence with that radio and lightly tap all wires every few feet. You'll probably find a place where you tap it and the noise returns. Look for bad splices or shorts in that area.

Good luck... hope this is some help.

StarGazer wrote:
"Is there a formula for the length I will have to cut? Is it 468/f?"

The ARRL Antenna Book says a wavelength in feet is 983.6 / F(MHz).

A 1/2-wave antenna is approximately 95% of 984-ft / 2, divided by the frequency in MHz. 1/2-wave antennas are thus about 468 / f(MHz).

The total length of the ordinary inverted-L is about 1/4 wavelength at first resonance. This in feet is about 234 / f(MHz).

StarGazer says "sctually an inverted-U".

If Stargazer is actually considering a folded unipole, he needs a 1/2-wavelength of wire to make a 1/4-wave antenna. ON4UN in "Low-Band DXing" has a nice graph of radiation resistance versus vertical height of the horizontal segment in wavelength (up to 90 degrees or a completelly vertical antenna). There is a lot more about this antenna also. This is the actual inverted-L, not the folded unipole.

Best regards, Richard Harrison, KB5WZI

Richard Clark wrote:
"---you have to measure the tension in service, and you already are there, you may as well measure the sag directly---."

Yes, but that may not be as easy as it sounds. It`s easy to measure tension. There are simple tensiometers which divert the sagging wire a bit and relate the tension in the wire to the diversionary force required.

Ed Laport suggests determining the frequency of resonance of the tight wire. He has the formula and describes how to pluck the wire and pick up the tone! From the tuning of the wire Ed can give you its tension.

I`ve only used the tensiometers, myself, and then mostly on guy wires. I was never much on cinching things up too tightly. As long as transmission wires didn`t strike arcs in the breeze and as long as antennas continued to work in strong winds, I was happy. Some would say I was sloppy, but my stuff worked problem free for the most part.

Best regards, Richard Harrison, KB5WZI

Richard Clark wrote:
"This seems to be a fairly circular specification."

The usual case is that a catalog will give the tension a wire withstands, its weight per unit length, etc. You can estimate how much wind, ice, roosting birds, etc may add to the weight of the wire in the span. These forces are offset by tension in the wire in removing sag. The tension in the wire can`t exceed the maximum specification with or without additional safety factors.

You can calculate the sag in advance and see if it is satisfactory. If not, stronger wire, shorter spans, lighter weight conductors, or some other adjustment will be required.

Best regards, Richard Harrison, KB5WZI

5081. Portable Antenna for FT-817

Newsgroup: rec.radio.amateur.antenna

From: N4IXT <n4ixt@arrl.net>
Message-ID: <am0tav$1p2db$1@ID-105647.news.dfncis.de>
Source record: 134621

Working on buying an FT817. I need a very portable antenna for it. Something small, lightweight, that I can quickly put up and take down in a motel room, and won't take up much space in luggage.

MFJ makes a nice one that's one 80 to 2 all bands in one antenna, attractive because I'd only have to carry ONE antenna around.

I fully realize that none of these small telescoping type antenna are going to be great performers, but I'm willing to exchange a little performance for the portability.

Anyone have experience with the MFJ or other "plug it in and start operating" type antenna?

Thanks,

Robert / N4IXT

Danny, K6MHE wrote:
"I am wondering if anyone has information on the amount of stretch involved in typical wire antennas using copper wire?"

Stretch of a wire requires loading the wire beyond its elastic limit so that the wire does not return to its original length when its load is removed. Staying within the catalog maximum tension ensures the wire will not stretch significantly.

This may be calculated when conditions that are normally encountered occur. The ice storm of the century may bring the wires down in spite of good practice.

Best regards, Richard Harrison, KB5WZI

5083. Re: looking for an multiband HF vertical, quick to assemble in a field

I like my Hustler 5BTV vertical. I use it for home, camping, and Field Day. It can break down into about a 3-4 foot package. Ground mounted, it performs well without radials and has decent bandwidth for all bands except 80 meters. Mark your preset assembly points with a marker for easy reassembly. I do not find a need for an antenna tuner.

The 5BTV is a good compromise antenna. It does not perform quite as well as dipoles or beams...but it will get you on-the-air.

An inverted-L is a 1/4WL vertical monopole with the top bent over
horizontally. The formula is approximately 234/f. To perform very
well, an inverted-L (like a 1/4WL vertical) needs a ground plane.

> How close to resonance in my intended band of 160 m do I

You might as well trim it to minimum SWR on your favorite frequency.

Here's an interesting 20m full-wave loop. 17ft horizontal top section
at 40ft high. 28ft side sections fed at the bottom intersection point.
Maximum gain is 7+ dBi and the feedpoint impedance is close to 50 ohms.

If I did that, I would run the coax straight down to ground, and
ground the shield at that point. You need a good low resistance ground
at that point. Then run the coax under or on the ground to the shack.
I would then treat it as any other antenna, and ground out at the
entrance ground when bad wx. "I don't bother with suppressors" Never
let the coax hang in the air as it goes down to the shack. That can
really eat your lunch. Myself, I don't think dipoles really get struck
that often. Or at least compared to verticals, but with the coax
grounded beneath the antenna, most of the strike will go to ground at
that point if it happens.
> >
>
> Fred,
> I think if you had grounded the shield of the coax where it enters the
> house the lightning would likely have been happier to go to ground
> right there.

It would be better to do it under the antenna. Lightning doesn't turn
well. Also, you don't want the lightning return ground to be at the
shack entrance.
I use metal masts or towers to support my antennas so I have a built
in lightning rod. The masts direct the strike to ground, not my
feedlines.
I have a ground at the shack entrance, but it doesn't have much to do
as far as directing the lightning to ground. It's just there to play
"cleanup" with what little is left over. Prevents possible arcing or
flashing, and ensures all is at the same potential. If you used
suppressors, they would be mounted there.

Yes, the approximately #12 wire might vaporize but the
> huge currents in the house are not what we want.

You should use #6.
> If I understand correctly, to paraphrase (I think it was the QST

> of electrons get into a traffic jam trying to get into the ground.

The best target will usually be the best streamer in the area.
Normally, a dipole is not that hot a streamer, unless you have some
sharp points of wire ends somewhere. A vertical usually is more likely
to be struck. I've never had a dipole struck yet. Maybe I'm lucky...

> just how much increase in length in percentages are we talking about?

This is a very tricky topic on which to make any black & white
statements because of the huge collection of variables which are
involved. First off the only effect stetching has is to shift the
resonant freq of the antenna or antenna element downward. Copperweld
wins by a large margin over any pure copper wire by virtue of steel's
much higher yield strength and Young's modulus given the same
cross-sectional areas. Which are *not* defined by the "gauge" of the
wire. From there ya get into the types of lays for stranded wires, the
effects of strain hardening on the physical behavior of the specific
wire, etc. It's a rat's nest in the field of applied mechanics which
is better left to the pros in that biz as far as the analytics are
concerned.

If you're really serious about digging into the matter as a ham your
best bet would be to run some simple tests on wires you might use.
String 50 or a 100 feet of it out and pull on it with increasingly
higher known loads by whatever means you have. The wire will stretch
to some minor extent at any load. And when you drop all loads the wire
will return to it's original length. To a point. In this operating
regime the wire will be in it's linear elastic stress range. But there
will come a load which permanently stretches the wire and it doesn't
snap back to it's original cut length.

That's the critical yield point load on the wire which you need to
avoid under the worst loading conditions you expect to encounter. It
goes farther, there is also the problem of fatigue . . . And
advertised "tensile strengths" don't mean much because by the time you
actually pop the wire it's already well past it's yield point and is
considerably permanently stretched.

I find out what the advertised "tensile strength" of the wire is via a
phone call or two then make sure the load on the wire doesn't exceed
20% of that number when I string the thing up.

hi,
I am writing a log-periodic antenna design pakage. but I do not have enough equations and I haven't decided which programming language to use yet.
I would like to have the equations of finding the surrent and voltage distribution of the dipoles when a signal of frequency f is recieved or sent. I also need the equations of finding the radiation pattern.
please help me if you have these equations. any suggestions of what to include in the pakage and the programming language to use are welcome.
thanks a lot.

5089. Re: Whats the formula for resonant length of Inverted-L?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-15 11:52:04 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <am1s93ngs1@knossos.btinternet.com>
Source record: 134630

The resonant length of an inverted-U antenna depends on wire diameter, length of vertical sections, length of top section, height above ground, and characteristics of the ground radials which will not be known very accurately

But for practical purposes you can forget all about antenna resonance and consider only overall length and the resistance of the crudely-known ground connection.

Your objective is to obtain a midband, 1.9 MHz, feedpoint resistance of about 50 ohms to match a 50-ohm coax. (Or 75 ohms for a 75-ohm coax.)

An exact 1/4-wave resonant inverted-U antenna almost certainly will not meet this requirement unless the ground connection loss resistance is in the order of 25 or 35 ohms. At least half the Tx power would then be wasted in the ground which you would not find acceptable.

A tuner will be needed at the junction of coax and antenna wire. If this is inconvenient all well and good. No problem. Just lengthen the antenna wire and shorten the coax. Saves money too.

An important feature of an end fed wire is that the resistive component of input impedance increases smoothly with frequency and the +ve input reactance increases something faster. So by experimenting with overall wire length a point can be found at which the antenna input resistance plus ground loss resistance is very nicely equal to 50 ohms. And the input reactance can be tuned out with a series variable capacitor. On 160m band a 500pF max capacitor will be fine. The overall antenna length with a reasonable ground loss resistance of a few ohms will be around 0.27 to 0.33 wavelengths. (Or in the range 140 to 170 feet.) Antenna length is VERY non-critical. You don't need formulas.

If you havn't the space to extend to a longer wire length then use an ordinary tuner. A longer than 1/4-wave antenna has another advantage. It brings the antenna input impedance right into the range of the ordinary sort of tuner. It is usually impossible to tune up a low, exact 1/4-wave antenna which has a low ground loss resistance.

If you like amusing yourself with numbers, download program ENDFEED which models verticals and inverted-L's. An L is as near to a U as dammit is to swearing. It takes into account number and length of ground radials. It calculates value of the single series tuning capacitor and the L and C values of three different types of tuners.

PS. One wavelength = 300 / MHz metres which is always good enough and allows a teeny bit for pruning.

On Yahoogroups there are several groups that discuss this very
subject.

Recommended groups are Buddy pole, HFPack, FT817, all have FAQs
and if you join you can search the archives. Personally I have used
the Buddypole, quite small to carry and works well, the Ventenna
equally small not quite as efficient, ATX very small poor radiator,
MP-1 by W6MMA small screwdriver type pretty fair radiator.

The HFPack groups is holding an antenna shootout at Pacificom
in October the results should interest you. The also held such a
shoot out last year and I believe the results are available on the
HFPack Yahoo group.

I hope this helps you out

An inverted L in these parts is a quarter wave up and a quarter wave
horizontally on it's fundamental freq. and has a very high Z
feedpoint. The inverted L you're talking about is a short GP with a
tail.

I would put up a dipole of 5 (6mtr) wave lengths or 30 meters...you will do pretty well with that or the longer the better, you may need a tuner to transmit on HF and one with 6 meters in it would help....any 5x (5 multiple) of 6 meters will probably work well for reception and still should load on 6...another Idea is to get one of these 80-6 meter butternut verticals...work great...73 Murray

NO it will not...you can make that antenna good all the way down to 6 meters if you will use ladder line to a balun (inside or outside the house) and a tuner.

A homemade dipole for 6 meters is small enough, you could orient it either horizontally or vertically, depending on which polarization would be best for you, horizontal or vertical. The commercial verticals would offer little, if anything, more, other than higher cost.

I probably won't be much help. I can't see why you have a device that causes that amount of loss on HF. Doesn't make sense to me at all. I was thinking the 718 had a preamp already in it. Most icoms do. "both my 730 and 706g do" Not to mention the front end is already hot on most icom rigs. There are many designs for pre-amps that would work, but it's not something I usually recommend. A good way to trash a perfectly good receiver. More images, etc, etc. I once built an HF preamp years ago, and I think I used MPE-152's???'s or something like that. I forgot...All it did was pump up the S meter, and basically trash out an already decent radio. "drake R4". It didn't do a thing as far as improving the s/n ratio. MK

I'd be wary though. I'm surprised you don't have image problems from
HF bands, using the large HF antenna. I first did this when I got a
706g, and the HF image problem was quite bad on 6m. Even at night!
When I went to a 6m only antenna, the performance was much better.
When I went to a yagi, it totally cleaned it up. I'd be wary if he's
using a ft-100. He "might" have this problem also. I don't know if the
yaesu's have this problem or not. The 706 sure did.
Also, I think a regular 6m dipole would outperform the 40m dipole in
general.
I'm guessing the 40m antenna could have the potential to be a cloud
warmer on 6m. Much the same way as I noticed an 80m dipole on 10m is a
cloud warmer. It was really bad performance. Wasn't really expecting
that until I tried it out camping one time. Anyway, maybe the yeasu is
better in that regard, but speaking for the ic-706mk2g, using a large
HF dipole for 6m use, is a big mistake. Trash city...MK

There was a misunderstanding. I was referring to the antenna wire as
being #12 and meant that if it is ever struck it will get vaporized
regardless of how the coax is grounded.
Others have pointed out that the coax should get a connection to
ground before it gets to the house - good point. It appears as if the
idea is to make it easier for the strike current to get to ground
outside and away from the house so that it doesn't come inside and
start hunting for ground there.

You've had a number of answers, but I didn't see any address
the concept of using the neutral for the safety ground.
Don't do it - doesn't matter if you're grounding an amateur
station, or a bench grinder, or a coffee maker or whatever.
The code requires a separate equipment grounding conductor -
it doesn't allow the neutral for safety grounding.

True, and it`s commonly understood that the usual inverted-L is resonated as a 1/4-wave antenna. This makes sense for use with ordinary feedlines. These range from 50 ohms to 600 ohms characteristic impedance. An end-fed 1/2-wave antenna has a drivepoint impedance of several thousand ohms due to a tendency to repeat the open circuit at its far end.

The inverted-L can be directly connected to the radio and avoid a transmission line in some cases. 6,000-ohm antenna impedance? No problem!

Best regards, Richard Harrison, KB5WZI

Well, I seem to have dropped 1/16 of a wavelength from my memory. The 15th edition of the ARRL Antenna Book sez: "The inverted-L antenna can be supported by any convenient means. Matching is easiest when the total length is near 5/16 wavelength". They make it a tad longer than 1/4 wavelength so the feedpoint impedance is 50+jXL and then feed it with a series capacitor such that |XC| = |XL|. From my experience, I would say that a 160m inverted-L is usually not 1/2 wavelength. So your parts must be different from my parts. :-)

I was just going to make it 123 ft long and feed it with 50 ohm
coax at the intersection of the ground rod and inverted-U.
Are you saying I'll need a series capacitor?
If so what is a good one to get and where??
I thought I could just tune it with just my MFJ989C tuner.

Brian Kelly wrote:
"It goes further, there is also the problem of fatigue . . . And advertised "tensile strengths" don`t mean much because by the time you actually pop a wire it`s already well past it`s yield point and considerably permanently stretched."

That`s a little pessimistic.

Fatigue only occurs when stress reaches a particular point. The practice is to keep stress below the point where a wire might suffer fatigue. Below this stress, a metal can be flexed an infinite number of times without fatigue.

Advertised tensile strengths are likewise not the design loads. These loads must not exceed the yield point because permanent stretch is usually undesirable.

As a matter of fact, tensile strength does not greatly exceed yield strength. This is because once the point is reached at which the material gives, it doesn`t take much more force to stretch the material on out and break it.

Best regards, Richard Harrison, KB5WZI

Boy, I second Mark and then some.

The noise level on HF is quite high. As long as you can hear the noise, then you have enough gain. Any more gain hurts, rather than helps. Turn on your radio, switch to 10 meters (the quietest HF band) and then plug in the antenna. Does the noise increase? If so, you can't use any more gain. Your receiver has a sensitivity of 0.16 microvolt. Even with your 10 db loss, you probably still have a couple of microvolts of noise coming into the radio. If the signal is below that couple of microvolts, you aren't going to hear it.

Now, what you will do with the preamp is amplify the noise. The signals, being stronger, won't get amplified as much as the noise unless they are very weak, then they will get amplified as much, but no more. So you will hear weak signals as well, and not so weak signals not as well, if the signal you are listening to is the only one on the band.

But it won't be. There will be other signals, and they will be more inclined to swamp the RF amp in the 718 or pump your AGC. You will get lots more intermod (the 718 isn't a K2 after all), so the net result of adding the preamp will be a much harder time, a lot less fun operating, and overall, a big loss in your ability to pick out the weak signals.

Years ago, when tube type receivers had sensitivity in the 5 microvolt region, a preamp made some sense. But with a receiver as hot as the 718, it makes no sense at all at HF.

At VHF/UHF, where the band noise is a lot lower, and the noise inside the radio a lot higher, then it may make sense. But at HF, it's pretty much always a looser.

..

Why not just built one? Tuners are pretty simple. Especially if you want
to dedicate it to the Inv. L only.

Then again if you make the Inv L wire about 185 foot or so. You may not
even need a tuner. I don't.

As usual, the problem is a little complicated. An antenna shaped like an 'L' can be any length. If you make the inverted-L 1/4WL, it will exhibit a feedpoint impedance of around 35 ohms thus giving a 50 ohm SWR of around 1.5:1. This is what I originally had in mind. You can use an antenna tuner but you don't really need one. An SWR of 1.5:1 is, IMO, perfectly acceptable.

Getting a little more sophisticated, if you make the inverted-L 5/16 wavelength, you can get by with a series capacitor and no antenna tuner. Pure-ists don't like antenna tuners. :-)

Make your inverted-L 5/16 wavelength and use a single series
cap. A doorknob cap would be a good choice.

Soft-drawn copper has a pretty low tensile strength no matter how you look at it. The original poster didn't mention what gauge wire so we are speculating about the exactness of what we already instinctively know.
On my old 20m quad, for instance, simply straightening out (pulling on) the #16 soft-drawn wire before installing it I gained a few inches.
I gather the original question was asking if the amount of stretch for copper vs copperweld was consequential in actual practice. I'd have to answer that over time yes, it would probably be noticeable (in spite of light tension) due to windstorms, ice, etc.
But I wouldn't grade the difference as enough to preclude using copper wire. That decision would depend on how particular the antenna owner is.

IMHO,
Bill

Actually, I was off on my initial 8-12 dB loss. It is more like 4-6 dB. The in-line device is an interference canceller, similar to the MFJ model, except home brewed. There is some loss, but I found that the orientation of the noise antenna makes a difference in the amount of total loss. It seems to work great on computer screen noise, but the power line noise I really wanted to eliminate is not even touched. Maybe the noise is too broadbanded (when the noise occurs I can hear it on all the Ham bands) . The Icom blanker won't eliminate it either, but the noise blanker in an HTX-100 10 meter rig eliminates it almost completely! I agree with posters that a preamp would definitely do more harm than good. However, my immediate goal is to get rid of this noise!

1) If you want *lightning* protection, you have to ground the
hell out of everything. The "hell" is the lightning, and if you
want to keep it away from your equipment, you need a huge
ground system and a very low impedance connection to it.
2) Alternative to 1) above is to keep all your equipment
away from the "hell". That means TOTAL disconnect of the
equipment and physical removal (distance) from the coax.

Both of the above are generally not feasible for most
amateurs. However, you can improve your ground system,
and you can disconnect, short the coax to ground, and
leave things in place. Those things will help, but they
don't guarantee that a nearby strike won't bite you.

If you do add a ground, driving a water pipe as you mention does not comply with code. You need to use the materials, methods and dimensions mentioned in the code, and the added ground electrodes must be connected to the house grounding electrode system as specified in the code.

In answer to your question #2 - see the above. You MUST provide a safety ground to the coax shield - thus your station ground and your safety ground must be tied together - per the code. See the National Electrical Code articles 810-57 and 810-58

5116. Re: Copper Wire Stretching?

Hi Richard,

This takes me back to my physics class where my prof introduced us to
this very notion, as part of acoustics or as he titled his chapter
"Wave Motion and Sound."
"We shall study various properties of waves using the stretched
string to illustrate. First consider the end of a string with tension
T pulled up velocity u. Now the motion of subsequent parts of the
string moves down along the string with velocity v. Using the
impulse-momentum theorem over a time t we have:
Fy * t = muf - mui
(T * sin (theta)) * t = (rho * A * vt) * u - 0
now using
ut/vt = tan (theta) = sin (theta) [for small angles]
we have
T * (ut/vt) * t = rho * A * vt * u
or
v = SQRT(T/rho * A)"

[where theta is the angular displacement of the plucked string; rho is
the mass per volume; and A is the cross sectional area of the string;
ut is the displacement wrt time; vt is the propagation wrt time]

Knowing the velocity and distance between anchor points, it should be
a short haul to finding the note of resonance. And I would offer a
further comment from my prof on that matter:
"Of extreme importance is the fact that the velocity of
propagation is independent of how fast the disturbance moves the
string up and down."

From this seeming trivial detail, we moved further to understand that
it was the shape of the pulse (the initial disturbance) that impacted
the amplitude of the resonance. Later, by some dozen years, the math
of Blackman and Tukey of Bell Labs matured into the Fast Fourier
Transform which fulfilled this correlation.

Anyone the newsgroup trolls disagree with.

They will argue that it is an "illegal CBer", but they attach the label
quite freely to anyone who disagrees with their antisocial tactics within a
newsgroup.
LEGAL CBers and radio Amateurs have often been given the label "keyclown".

You will notice that the post makes accusations of pimping and drug use, and
is nothing more than a string of insults hurled at anyone who will take the
time to read it.
Some "antikeyclowns" have even been caught promoting illegal activity
themselves, which leads me to believe that their whole "pro-legal" stance
is fake, they just want to cause arguments on newsgroups. One of them has
made several attempts to spread the anger to a UK group, but has just been
blocked by most of the users.

Regards,

Peter.

5118. Hamsticks-Any parts that can go "poof"??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-15 22:53:34 UTC
From: DipoleDude@webtv.net
Message-ID: <20440-3D850F6E-500@storefull-2353.public.lawson.webtv.net>
Source record: 134659

I've been going through a mind boggling week, trying to diagnose an antenna situation. I've been using two different antenna mounts, one on each side of my SUV's luggage rack. For many months, I've used two Lakeview Hamsticks, one for 20 meters and one for ten, and used a coax switch inside the vehicle. I was able to obtain a match of 1.5 to 1 or less over the entire bands for each antenna.
Last week I got fed up with "spanking trees" all the time because of their height. In an effort to reduce that, I moved the antennas farther to the back, and put them on a 45 degree angle. I never re-checked the match after doing this. I later learned that this section of the luggage rack was plastic and not metal as with the previous installation. So my match MUST have been off.
NOW, neither antenna works properly, EVEN after moving the mounts back to the original spot. I get a 3 to 1 match, over the ENTIRE band with the top elements all the way down...or all the way up.
Not the coax. Replaced that. Not the coax switch. Took that out. BUT...I replaced the the antennas with a couple of "Firesticks" I picked up at a truck stop a while back. I adjusted one for 10 meters, and got a nice 1.5 to 1 match on that. And adjusted the other, with the help of a 6" threaded rod, to work 12 meters with an SWR of 1.9 to 1. Had several QSO's on both antennas.
Now I'm really wondering if something has gone "poof" on the Hamsticks. How well does the inductor hold out on these Hamsticks? Can they handle a significant mismatch? (I was only running 100 watts.) Are there any small capacitors used in the antennas?
Thanks for any help, advice, flames.

Mike

>for the rest of the bands.

Hi OM,

Keep your current tuner for general use and build a fixed tuner for 160M (or perhaps semi-fixed). Move this one step further and build the fixed tuner at the antenna and skip the line loss due to SWR. Such a fixed tune may allow you to use the general tuner for band edges (speculation on my part).

However, I doubt this remote tuner is what you had in mind as I suspect you want to make this a general coverage antenna (an emergency 6M radiator too). Without a remote switch, a fixed remote tuner gets in the way. Plan with remote switching in mind and you can waltz away from a lot of problems.

If the 50 ohm match has changed, then something has changed at your hamstick.
I have not heard of them "blowing up" because of a mismatch, but it might be possible at high power levels. I would make sure the ground to the vehicle is solid, and the hamstick is mounted exactly as before. The tuning on my mobile antenna is quite sharp because it is physically small, it does not take much to change things, you have changed things around.
One way to check things is with an antenna analyzer, such as the MFJ 259b.
It will tell you what is wrong, by the R+/-JX display. Before everyone jumps on me, you must determine the sign of jx, which is not too difficult.
An swr bridge will tell you something is wrong, proper intreptretaion of an antenna analyzer will tell you what is wrong.

Richard Clark wrote:
"Knowing the velocity and distance between anchor points, it should be a short haul to finding the note of resonance."

Ed Laport has distilled the tension formula to something short and sweet:
T = 1.006 (t/N)squared, where---
T = tension in pounds
t = time in seconds for
N = number of complete vibrations of the whole span.

"Snap the wire at its mid-point by pulling it to one side and releasing it. At the moment of release a stop watch is started, and the number of complete swings of the wire are counted (say 10 vibrations), at which moment the watch is stopped,"

I almost always used a tensiometer to indent a prescribed length of wire and the force required was calibrated in pounds tension of the wire.

With guy wires, I`ve actually used a come-along on the guy wire and attached a scale between the come-along and guy-anchor. All that`s necessary is to see how much tension is required to relieve the turnbuckle tension on the anchor.

Best regards, Richard Harrison, KB5WZI

Nope. Didn't mix 'em up. Got 'em all well marked.
When I put them back in the same spot, I even took the time to wire brush (with cordless drill) the metal of the luggage rack to make sure I was getting good contact. I have tried EVERYTHING to change the 3 to 1 match. I have tried counterpoises, mag mounts, grounding to frame, adjusting the top whip fraction of inches at a time. The 3 to 1 match is static, never changing. Never higher, never lower. (Same with the power output: Just under 20 watts...never higher, never lower.) It's the same at the top of the bands as it is at the bottom.
I'm just curious what the inductor is like on the inside of these Hamsticks. Perhaps the wires have fried and shorted? I'm just not sure what happened. The rig is working PERFECT with the "Firesticks" on 10 and 12 meters. Just by the process of elimination, the Hamsticks themselves are the only things left.

Which code is that? NEC? I've never heard of that one before. If that were true , half the plugged in items in a house, washer, driers, etc, etc would all be out of code. Here, I use nothing but the nuetral for safety grounding. Of course, you have to check to make sure it's really grounded. But say in a bathroom with testable sockets for fault protection, if what you say is true, those would be illegal. But I see them installed in new houses, and they seem to pass code. I use the nuetral wire to safety ground my henry amp. Thats what the "3rd" ground plug is made for. But I also have no doubts about the integrity of my nuetral ground wire though. I ran the wire myself. I've never seen instructions for a coffee maker require a "stand alone" ground. In fact, most coffee makers don't even have a ground pin on the plug. They don't provide a ground lug either. I know an electric furnace installed , and grounded only by the nuetral wire passes inspection in Houston when inspected by the city. "They are inspected by the city, but according to state code". This rule is a new one on me..I see no problem using a neutral for safety ground. It's ground, just like any other one...Just make sure it's actually wired right though..Most of the plugs in this house don't even have ground pins. It was built in 1959. My henry does only because I ran the wire to the box myself. The washer/driers out in the garage also have ground pins. Thats about it...When I ran 117v gear that had to be grounded, I used a seperate ground because I had no choice. MK

==========

A coax inner conductor sliding inside a tube is fine as a small high-voltage variable capacitor.

But if a high current flows, as in a magloop, the loss in the capacitor will be appreciably higher than in a capacitor with both plates having similar areas.

The thin wire has an abnormally high resistance but it has to carry the same current as the very large conductor diameter in the main magloop.

The problem can be partially overcome by cutting a length of coax into a number of pieces and connecting them in parallel.

Mike,
When I got a Hamstick there was a caution note about installing the stinger: it mentioned to be careful not to damage the wire that transitions from the coil to the fitting that holds the stinger. Perhaps at some point in handling the antenna's this got damaged - though it seems unlikely to happen in both and at the same time. Do you have any friends with the same Hamsticks so you could put those in your mount and check them out?

Good luck,
Howard

The mast is not the broblem. How far from the boom and what frequency for the beam? It makes a big difference. If it's an HF beam, or VHF, or UHF

>. And about 3 feet below a 2 element beam.
>
> This shouldn't be a problem for either antenna should it?

I'm having to guess as I need more information.
Yes. In theory it should lower the impedance and distort the patterns of both antennas and it most likely will in practice IF the 40 meter antenna is only a few feet below an HF beam there most likely would be some problems

My tribander is 15 feet below the 6-meter antenna and the 6 meter antenna is 12 feet below the 2-meter array. My wire antennas end about 30 feet below the tribander and are at roughly at a 45 degree angle to the tower.
.>
> Since there shouldn't be hardly any mutual conductance since
> they are perdicular to each other.
>
Or are you referring to the boom? If so then yes, you are going to be using the 40 meter antenna as a counterpoise....

Unfortunately all this is moot until I know What frequency for the beam, the size of the beam, how far the 40 meter antenna is from the beam. The vertical mast is no biggie. I have a 4 meter inverted V hanging just a few inches out from a ROHN 45 G and it works fine. Yes, it would be better to at least put the thing on an arm and put the antenna a few feet out.

If interested, see:

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=1381573182&ssPageName=ADM
E:B:LC:US:1

It has not been used in the outside elements/weather and has never been
mounted to anything. The whip antenna is in perfect condition as it has
seen little use. I bought this antenna about three years ago and used it in
the radio room (with the antenna module sitting on the floor) for one month
before putting up a dipole and buying a Kiwa MW Loop antenna. I just tested
the unit with 6 AA batteries and it works perfectly. The unit comes in the
original box and has the original manual.

> Which code is that? NEC? I've never heard of that one before. If that
> were true , half the plugged in items in a house, washer, driers, etc,

Electric washers and driers - to comply with code, must have an equipment ground. If the outlet is only two conductor, as you often find in older houses, then there must be a bonding wire from the frame of the washer or drier to a legal electrical ground. This if often the cold water pipe next to the washer and drier.

> etc would all be out of code. Here, I use nothing but the nuetral for
> safety grounding. Of course, you have to check to make sure it's
> really grounded. But say in a bathroom with testable sockets for fault
> protection, if what you say is true, those would be illegal. But I see

There are GFI outlets that are designed for 2 wire systems. They do not require the grounding conductor to function well. I installed them in my house, as it has only two prong outlets.

> them installed in new houses, and they seem to pass code. I use the

No new house will have two prong outlets.

> nuetral wire to safety ground my henry amp. Thats what the "3rd"
> ground plug is made for. But I also have no doubts about the

The third prong is for a safety ground. It is not for tying the common and safety ground together to simulate a safety ground.

> integrity of my nuetral ground wire though. I ran the wire myself.
> I've never seen instructions for a coffee maker require a "stand
> alone" ground. In fact, most coffee makers don't even have a ground
> pin on the plug. They don't provide a ground lug either. I know an

Nor do many kitchen appliances. If there are no external metal parts that can be contacted by the user, then the safety ground is not required for most (but not all).

> electric furnace installed , and grounded only by the nuetral wire
> passes inspection in Houston when inspected by the city. "They are
> inspected by the city, but according to state code". This rule is a
> new one on me..I see no problem using a neutral for safety ground.

You are confusing the common conductor with the equipment ground conductor. While both are at ground potential at the distribution panel, they are not interchangeable.

Not all equipment requires an equipment grounding conductor (safety ground) - only those where a person could easily be exposed to an electrical shock due to a mechanical or electrical failure inside the equipment.

There is one major difference between the common conductor (white) and the grounding conductor (green/bare). It is allowable to wire the common conductor at fixtures so that the chain back to the distribution panel is broken. The connections can also be made with wire nuts or other removable connectors.

This is not the case for grounding conductors.

The electrical codes in the US specify that this conductor be contiguous from the furthest fixture on the feeder all the way back to the panel. If you remove a fixture in between, the grounding conductor must remain intact. All branch connections from the feeder grounding conductor must be permanent - which usually means a crimped connection. Wire nuts and other removeable connectors are expressly prohibited.

> It's ground, just like any other one...Just make sure it's actually
> wired right though..Most of the plugs in this house don't even have
> ground pins. It was built in 1959. My henry does only because I ran
> the wire to the box myself. The washer/driers out in the garage also
> have ground pins. Thats about it...When I ran 117v gear that had to be
> grounded, I used a seperate ground because I had no choice. MK

Sometimes, the electrical outlet box is grounded to the equipment grounding (safety ground) bus in the panel. If that is the case, then you can either replace the outlet fixture with a three prong fixture, or you can use an adapter that has a grounding wire that is screwed to the center screw of the outlet fixture.

This is rather sketchy, and possibly poorly worded. Please post a followup if you have any questions.

There is a reason for adjusting multiband, single mast verticals starting
with the highest frequency band. Think about it. It is the same reason
that you do the same thing with trap dipoles.

The noise eliminator should wipe out power line noise as well - assuming
that the source is close enough that it can be received by your sense
antenna.

If it can, then you must be doing something wrong in adjusting either
your phase or gain of the inverted signal.

Howdy!

I wish to install two antennas on my full-size pickup truck fiberglass camper shell. One is a 2m/70cm dual bander at 50w/35w and the other is a CB antenna and standard CB legal maximum. My questions are:

1) Can I make a good enough ground plane by making radials out of wire attached to the inside roof of the cap, or should I just get a large metal sheet and attach it on the underside of the roof?

2) How far apart do these antennas need to be if I plan on operating them both at the same time?

Thanks for any help,

Tad

I can eliminate computer and monitor noise completely, but it won't touch the power line noise. Of course, I've only been using a 5 foot piece of wire as the cancelling antenna. Perhaps if I went with a larger antenna, I might get results but then I don't want to start cancelling the signals I want to receive.

> If it can't, then you must be doing something wrong in adjusting either
> your phase or gain of the inverted signal.

The power line noise is apparently some distance away because no adjustment will affect it.

Mike,
There are no capacitors, etc. on a 'Hamstick'. You might
check to see if the conductor is still making good contact
at the base ferrel(?), about the only mechanical area except
for the 'stinger' getting inside the coil at the top. Tilting
the antennas at a 45 degree angle will definitely mean retuning
the antennas. If/when you do, rememeber that the 'stinger' can
NOT belowered too far. If it extends down enough to get into
the coil of the antenna, you have to cut the 'stinger' off. It
sounds like that may be what's happening...

Hi, all concerned:

Thank you for the responses, public and private. It appears that the electric fence may be one of those incidental-radiation devices, and thus "require" the owner's cooperation in my attempts to quiet it down a bit.

The tips given include rounding corners of the pulse, making sure insulators, grounding and wiring are good, cutting away foliage that could touch the conductors, and poisoning the horses -- no, just kidding on that last one ;o)

Thanx v.m. again.

73, Dave, N3HE

I beg to differ, there is nothing professional about making what could be an
easy job a hard one.

What is *professional* about taking for ever making up "cards" for NEC when
another program allows you to "draw" the antenna ?

I actually tried to use it again over the weekend and found once again
it a real pain to use.

I shall have a look at some of the other stuff you mention, that looks interesting.

> Any program no matter how *nice* the user interface may be is of

Very true, but as of yet nothing has been proved to inferior in its results.

My prefered sofware produced realistic results with in my opinion a superior
interface, nothing wrong in that.

Regards...

Source record: 134587

Hmmmm...that's interesting Mark. I have had no HF image problems with the FT-847 at all. It's clean as a whistle. As far as being a cloud warmer, I don't see how that could possibly happen. The take-off-angle of a horizontally polarized antenna is primarily a function of height above ground, not the length of the antenna. This does fall apart considerably when you use an inverted vee, however. This is a VERY important point. Once you "invert vee" a long center fed dipole, you WILL generate all sorts of high angle lobes. If kept flat, the antenna has the same take off angle(s) as predicted by the equation below. Subtitute 2, 4, 6, 8 etc for the first null, and 3, 5, 7, 9 etc. for the 2nd lobe, 3rd lobe etc.

Your experience with the 80m dipole on 10m makes sense if it was put up as an inverted vee. If it was up in a flat-top configuration, then it should have performed quite nicely on 10m at relatively low angles. I experienced the same thing myself when I first tried multi-banding a balanced feed, 135' inverted vee. It stunk on many of the higher bands. I couldn't figure out what was going on. I modeled it and it looked terrible on the higher bands. Where was all that gain going? AHA! I looked at 45 degree elevation and whoa! Lots of gain. I then took out the "V" and made it a flat top. 45 degree elevation lobe disappears, all the gain is concentrated at the low angle lobes as it should be and as described in the equation below. Lesson learned: if you are going to get good performance at low take off angles on a "long" dipole, you better keep it flat.

This is one of the problems with the "all-band" 135' balanced center feed antennas that people seem to love. If you don't put them up as flat-tops, their performance on the higher bands at low angles is dismal.

TOA= arcsin(1/(4*h)) for the first lobe, where h=height in wavelengths above ground. (flat tops/yagis/logs/quads etc) not for inverted vees)

I modeled my 40m inverted vee on 6m and found it to be pretty much what I expected. A flat top is always better when being operated well above half-wave resonanace. An inverted vee will warm the clouds as well as radiate reasonably at low angles, in some selected directions, however. The flat-top is always better in maintaining low angles when being used well above it's fundamental freq.

On 6m, the 40m antenna has lots of lobes and nulls, 4 to 7 dB gain in the lower angle lobes (at selected azimuths, of course) and considerable gain at some high angles in some directions. It is impossible to describe accurately in words, but what you get is several lobes in the vertical plane, as well as several nulls, each associated with a particular azimuth. That's the nature of "long wires", and the extra high angle lobes are a function of using an inverted vee configuration as opposed to a flat-top.

In short, for no additional work, you have another band on which the antenna will work nicely in many directions and elevation angles and not so nicely in others. I have had no intermod/image/overload problems whatever on my FT-847 with this antenna, nor did I experience anything like that on my TS-870s when I was using the 90' center fed flat top on 6m . I LOVED that 20m extended double zepp on 6m. If I heard them, I worked them, period. Of course, if they were in one of the deep nulls, I didn't hear them <g>.

I'm not suggesting this as a cure-all, but as an acceptable compromise antenna if you don't want another feedline and already have a 40m dipole up. Surely a 6m dipole up in the trees or hung off anything 20' or so above ground will be a better choice.

All my comments about the 40m dipole are purely speculation when it comes to making contacts. The 20m Extended double zepp was proven on the air. The 40m inverted vee has yet to make a contact...I just was goofing around and discovered the nice match it presented and proceeded to do the modeling afterwards. The model confirms what I was expecting and what I got from the 20m EDZ. Good match, lots of lobes and nulls in both direction and elevation. It should make many contacts possible for no additional investment in time and money.

If there is one thing that I think is most important for those who are going to play with long center fed wires, it is DON'T USE AN INVERTED VEE CONFIGURATION, unless you don't care about low angle performance.

Now, we need 6 to open up!

73, and thanks for your comments.

Good point, Doc. I do have some shorter "stingers" (I haven't heard this nickname for them...) that may give me an idea as to if they are too long.
Again, I put them back to where they were...wire brushed the paint off to make even better contact...they are now totally vertical once again...and the problem STILL exists.
Almost reminds me of the time I fried the pi-network coil in an old DX-60A after forgetting to put the antenna on the back. (I was only 13. And I bet some of you guys STILL forget to put the oil pan bolt back in and dump five quarts on the ground...)The meter was flat on every band. No matter how you tuned it, it remained exactly the same.

Well Brain since you have only been around for a
short while I'll fill you in. The "Keyclownbuster" is a
Ham named Doug Adair N8WWM. He was flooding
the newsgroup a year or so back on a daily basis with
the same foul language accusation and insults. He has
lost his AOL account, Concentric, UUnet now he's
working on another one.
Now what I find strange is, that Doug and a couple
of others are ham operators, now just because they are
hams doesn't mean that they are morally right, but they
wouldn't and couldn't talk like this on the ham bands, let
alone on the cb or for that fact in person.

5152. Follow-up Disk Skin Effect Experiment

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-16 15:05:50 UTC
From: rsparks <rsparks@elltel.net>
Message-ID: <3d85ef54_2@corp.newsgroups.com>
Source record: 134593

This posting presents a report on "The Closed Loop Disk Skin Effect Experiment".

This is a skin effect experiment to confirm the results of the "Impenetrable Metal Plate
Experiment". The original experiment was reported at

http://www.televar.com/~rsparks/public_html/Disk_Experiment.htm

It was extensively discussed on the rec.radio.amateur.antenna newsgroup under the subject "Skin
effect experiment with disk on antenna".

The experiment reported here is a follow-up from the earlier experiment and incorporates changes
and suggestions following from the discussion. Neither of the two experiments detected any
shielding from the skin effect phenomena.

Why bother with an experiment?

Many of the newsgroup respondents are convinced that metals are a shield to electromagnetic
fields only because of "skin effect". Skin effect is the tendency for current flowing parallel to
conductor surface to flow mostly near the surface of the conductor, a tendency which increases
with frequency. Skin effect is well supported with a mathematics explanation
and experimental
measurements as the cause of increased resistance at higher frequencies in conductors, especially
feed lines.

A question arises when skin effect is cited as the reason that conductors can be used as a shield,
or when skin effect is described as being so effective in separating the surfaces of a conductor as
to make possible inside and outside currents on a coaxial cable shield. This experiment is
designed to test if skin effect can be detected when the applied voltage is normal to the surface of
the conductor. In other words, will a voltage applied to two sides of a flat conductor drive a
current directly through the conductor, or will the current be forced to flow around the edges of

the conductor because skin effect will prevent a direct path?

The Experiment described.

It was reasonable to assume that two identical circuits except for the presence or not of a test
disk, would compare the effects of the disk. Therefore the properties of the disk could be learned
by subtracting the properties of the circuit without the disk.

One 12 inch diameter copper disk previously used in the original experiment was used as the test
plate. The thickness of plate was 0.062 inches, about 10 times thicker than the shielding wire
used in RG-58 coaxial cable. In series with the disk was placed two 100 ohm resistors in parallel
to give a 50 ohm resistance. 24 inch leads were attached to the disk and resistor on each side,
and were brought out normal to the plate, then curved back on each side to form a circle which
connected to 3 1/2 inch leads from the test meter. The test meter was the Autek Model VA-1 RF
Vector Analyst.

The circuit was laid on a 1/2 inch thick piece of laminated press board. The path of the wires was
traced onto the board to aid in keeping the circuit wire lengths the same both with and without
the disk present. The disk was supported vertically in a slot cut in the board . The test board
was supported on a cardboard box to minimize nearby couplings. A picture of the test setup is
included with the complete report which can be found at
http://www.televar.com/~rsparks/Follow-up_Disk_Experiment.htm.

Improvements over the first experiment

1. Only one disk is used so capacity between disk is not a issue.

2. The circuit is a closed loop whereas the original experiment was an open circuit dipole which
is much more subject to external influences.

3 Direct measurements are used whereas the original experiment compared resonant points.

4. The disk is at the lowest voltage, highest current location on the loop to better balance capacity
to the loop elements.

5. The experiment is much easier to duplicate.

Results
No Disk With Disk

Frequency R X R X
MHz Ohms Ohms Ohms Ohms
1 49 -7 49 -7
2 57 18 58 18

5 49 49 49 49
10 50 97 50 96

15 57 138 56 136
20 43 199 43 199

25 77 259 77 256
30 78 282 79 279

Conclusion

Within the limits of accuracy of the meter, the two circuits tested as being identical. If skin effect
shielding were occurring, it would have forced the current into a longer current path which
would have been detectable as increased resistance and increased positive reactance, making the
impedance of the two circuit versions unequal. Without some indication of difference between
the circuit with the disk and the circuit without the disk, the conclusion must be reached that skin
effect shielding does not occur for the thickness of disk material and frequency range tested.

'Druther be both pessimistic and suspicious when it comes to hanging wire, beats having to do it over. Especially in the middle of a hot run a 2AM in a dx contest in the middle of February with ten inches of snow on the ground and more enroute . . Been there . . Done that . .

> Below this stress, a metal can be flexed an infinite number of times
> without fatigue.

You're on the right track but there are stresses and then there are stresses. There is a big difference between the effects of the static stress one imposes on a wire when it's suspended in, for instance, still air. But then the wind whips up and the wire gets into aerodynamically-induced vibrations and now the wire is under cyclic stresses on top of the static stresses. All hell can break loose if the total of the two stresses exceeds the specific endurance limit stress of the wire material(s) given enough cycles. The problem with this finding out what that endurance limit stress is for a specific wire. You can't do that unless ya know exactly what the material is by the numbers and can look up it's endurarance limit in the materials handbooks. If it happens to be published somewhere.

> Advertised tensile strengths are likewise not the design loads. These

> on out and break it.

I don't agree with that as a generalized statement. It's a huge variable when it comes to all the different types of wire used to make antennas plus it's a function of the particular ductility of the material and in the case of stranded wires also the lay. Which is to

say that in some cases with very ductile materials & constructions like fully annealed stranded rope-laid copper wire the delta loads between the Yp and the break stress can be very significant, i.e., ya can get a helluva lot of permanent strain between the 2% offset point and the "pop point". But given a cold-worked steel wire like Copperweld yes, the Yp and the Ut loads can be very close to each other.

One can "engineer" all of into oblivion, it's almost as much fun as "engineering" baluns the only difference being the engineering disciplines involved. Me I call Pres the Wireman, ask him what the rated break strength of the wire is and try to keep the load below 1/5 the rated break strength. Ain't failed me yet.

> pipe sections.

Might I suggest a base-loaded, 8-ft whip? Not
"optimum" from a radiation efficiency point of
view on 75 meters, but quite adequate there.
And the efficiency improves remarkably on 40
and above. I use one on my 4WD pickup that
regularly does battle with the palo verde trees
here on the Arizona back roads and trails.

The base-loading coil I use is the 6"
Texas Bugcatcher from Henry Allen in
Caddo Mills, TX. I also use his small
6" extension between the spring and
the coil to lift the coil away from
my pickup's metal fender.

You will definitely want to use a sturdy
base spring. I have had good luck with
the heavy-duty model from:

http://www.cal-av.com/springs.html

You may also want to stock up on 9-ft whips
at your local CB shop. That's the "expendable"
part of the system, although they are pretty
tough and can be straightened-out (kinda)
after a close encounter.

But again , I'm talking 240 volts. But I think I see what he means now. I think he's referring mainly to 120 volts. And using the nuetral as a safety ground. I don't do that, although they both ground to the same place in the breaker box. I'm thinking more in terms of using the nuetral for safety ground in a 240 volt line. I'd never heard of any problems doing that. MK

This sort of sounds like it could be the problem. I'm wondering how both could break at the same time also. Maybe they have been broke a while, and he just didn't notice it until now? It would be easy to check. Just ohm out the antenna from the base to the stinger connection. Burning up the winding itself is not very likely. If it's not that, sound like a bad coax connector somewhere. But that could be easily checked also. MK

Mark,

A long time quirk in the NEC allows 240 volt electric dryers, electric ranges, electric cooktops, and wall-mounted ovens to be connected in the manner you outline below. This is no longer permitted for new installations, but it is expressly grandfathered for existing installations.

No other household equipment can be installed in a manner that connects the safety grounding conductor (green or bare) to the neutral grounded conductor (white) at the equipment. This means that linear amps, large power tools, and so on generally cannot be installed without a separate grounding conductor.

The NEC is about a thousand pages long, so there are a zillion exceptions and special cases. For most household purposes, however, the grounding conductors and the grounded conductors are connected only at the breaker box.

Historically, local codes have been all over the place. I think most municipalities have now adopted the NEC as the basis for local codes.

Mike,
Since things never seem to change, I'd try a different
meter just for 'grins'. Also, you might check to make sure
that connections to the antenna are really good. You should
see a difference by just standing close to the antenna, it
shouldn't stay the same all the time.

Sorry to tell that attenuation on 160m due to high SWR on parallel lines or even coax (using an antenna tuner between transmitter and line of course) is close to peanuts. Putting the tuner at the antenna isn't worth. Just have a look at "Reflections (I or II)" written by W2DU.

Why is it so difficult to simply add a small physical capacitor to the
standard dipole to test your assertion - or is going there a challenge
to maintaining your theory?

>
>2. The circuit is a closed loop whereas the original experiment was an open
>circuit dipole which
>is much more subject to external influences.

Absurd by half. You are awash in the large wavelength components of
the experiment, you cannot escape that simple consideration. Whether
of not this is meaningful is not examined by you and constitutes a
standard blindside of taking data. I will take care of this for you.

>
>3 Direct measurements are used whereas the original experiment compared
>resonant points.

A non-sequitar, meaning nothing. For instance, how did you get the
original resonant points without direct measurement - using a ouija
board?

>
>4. The disk is at the lowest voltage, highest current location on the loop
>to better balance capacity
>to the loop elements.

A non-sequitar, meaning nothing. There is no relationship between the
magnitude of the current and balance - except as a function of poor
design. This suggests you are comparing a broken premise with science
and finding the broken premise supports your theory - it's still
broken any way you look at it.

>
>5. The experiment is much easier to duplicate.

It seems all of these improvements are for your ease rather than for accuracy. As none of these enumerated benefits actually change anything, they are a zero-sum gain. AND, as will be revealed, they did nothing to advance your theory one jot.

As far as accuracy goes, you simply accept the manufacturer's specification as gospel without examining it (which I will do following). This is "faith based" science....

Interleaved with your data is a simple EZNEC model of the same physical model (unfortunately employing a square loop, meaning it is somewhat larger, but not significantly so as the numbers reveal):

Impedance = 62.99 + J 249.5 ohms Impedance = 55.58 + J 251.6 ohms

>
>
>Conclusion

Well, we will skip your revisionism as the two sets of data support each other AND conventional physics that includes the skin effect. Your assertion that there "should" be a difference is revealed to be a flawed logic.
>

Hi Roger,

The comparison of the size of the disk to the wavelength (even at 10M) is overwhelmingly insignificant. There is no way on god's green earth that you can escape this at these huge wavelengths. 2M would be far more productive as the LOWER frequency limit for the size disk you offer. Translation: you haven't even come close to starting.

You still need to do something different. Here, you haven't really, you've merely shuffled the same broken premise into a new presentation that obviously stands with convention in glaring contrast to your assertions.

>pin on the plug. They don't provide a ground lug either.

Right. These appliances are probably similar (construction- and code-wise) to "double insulated" electric hand tools. Quite simply, they aren't grounded - the chassis "floats" at a high impedance.

> I know an
>electric furnace installed , and grounded only by the nuetral wire
>passes inspection in Houston when inspected by the city.

I find that surprising, if by "grounded" you mean that the neutral is actually tied to the furnace chassis.

> "They are
>inspected by the city, but according to state code". This rule is a
>new one on me..I see no problem using a neutral for safety ground.
>It's ground, just like any other one...

The problems are two-fold.

First, is the catastrophic problem you've referred to - a hot/neutral reversal. If the two wires are switched in the wall wiring somewhere, the wall-outlet "neutral" pin jumps up to 120 volts above ground. If you've "grounded" the equipment chassis to the neutral wire in its power cord, the equipment chassis becomes "hot". You risk lethal shock (if you touch the chassis at the same time you touch anything which is truly grounded), fire (if you interconnect this equipment with anything else which is grounded), etc.

The other problem is that neutral is _not_ ground, much of the time. The neutral pin/wire is at ground potential _only_ when no current is being drawn through the circuit. As soon as you start pulling current (through the "grounded" appliance, or through anything else on the same circuit), I/R voltage drop in the wiring "pulls" the neutral up above ground, by as much as several volts. This will cause a voltage differential to appear between the neutral-"grounded" equipment's chassis, and any "real" ground nearby. If the equipment is connected to any other grounded device, a current will flow through this connection... in effect, turning this additional connection into the neutral-return part of the house wiring.

It takes surprisingly little current through the human body to create a risk of dangerous shock. If you were to be touching a neutral-grounded appliance, and a "real" ground at the same time, and somebody turned on a big motor or electric space-heater on the same circuit, you could end up feeling a distinct shock... and it's even possible that the initial inrush surge would create enough of a shock to trigger cardiac fibrillation, if the current happened to flow through your torso.

Glad to here the good news. You might find it even better if you don't
double back. (Unless you are using it as a loop).

Like new MFJ 1.5kw dry dummy load for sale. It belonged to a friend who never followed through on getting his ham license.

$35.00 shipped CONUS. (Retails for $69.95.) Hi-Res (1600x1200) jpgs available on request.

Email direct if interested. KK4TL@AOL.COM

>safety grounding.

Yes the NEC says that a safety ground must not carry ANY current. That is the difference
between the safety ground and the neutral wire. The neutral wire is always carrying current
equal to the hot wire.

The reason that the neutral wire should not be used as a safety ground is because it DOES carry
current and there can be a difference in potential between ground and the neutral wire at any
particular location in the house. Voltage drop in the neutral wire from a load on the circuit.
While this voltage drop may be small in normal operation, it could become very high if there is a
poor connection between your location and the service panel. This voltage would come from
some load connected further down the line.

If the neutral line opened completely between your location and the service panel you could see
the full voltage from a load being turned on at some point further down the line from you. If you
had the neutral wired as the safety ground then the appliance would be at the full line voltage!
That is the reason for the separate safety ground.

There is one exception to this. Electric stoves. They use only 3 wires and do use the neutral as
the safety ground. All the elements are 220 volts so normally no current flows in the neutral line.
But there are sometimes 120 volt timers or outlets on the stove so then the neutral line would
carry some current. But the line to the stove must be a dedicated line directly from the service
panel. It must not be connected to anything but the stove. This is how they (NEC) justify this
setup. I think now though that a 4 wire circuit is now being used with

a separate safety ground.

Some hams wire their amplifiers to 240 volt circuits with 3 prong air conditioner plugs. That
circuit is two hot lines and a safety ground (at least it should be) . No neutral. This is fine if the
amplifier has no 120 volt connections inside. Sometimes a 120 volt blower is connected from
one side of the f240 to the center tap of the transformer primary in the amp. The transformer
acts as an auto transformer to run the blower. Again this is fine. But if there is any 120 volt
connection, then you must use a 4 wire circuit with a separate neutral wire to carry the 120 volt
load. You don't want the safety ground to carry any current.

The only reason that your furnace would not have a safety ground is if it has the power run to it
in metal conduit that is grounded. That would provide the ground. Otherwise it should have a
ground. If the inspector passed it he did not know what he was looking for. Not uncommon.

GFI breakers do not require a ground connection to work. They operate if they see a difference
in current between the hot and neutral lines. There must be the same amount of current in the
neutral line as there is in the hot line. If not that indicates there is leakage somewhere and the
breaker trips.

Double insulated appliances like coffee makers only have a two wire plug. Both sides are
insulated from ground and no separate safety ground wire is used.

Anything with a 3 prong plug requires a separate 3rd wire safety ground. Don't use the neutral
as a safety ground! That is worse than no ground at all.

I had another e-mail that said that 3 wire washer/drier setups "used"
to be legal, but are not now, in new homes. He said older houses were
grandfathered in. So this was a new one on me. I guess I'll have to
consider that in the future. MK

Roger, W7WKB wrote:
"Without some indication of difference between the circuit with the disk and the circuit without the disk, the conclusion must be reached that akin effect shielding does not occur for the thickness of disk material and frequency range tested."

Edison could have said a practical electric incandescent lamp is impossible because the cotton filament quickly burns out.

In the era of glass-envelope vacuum tubes, metal shields were effective in avoiding oscillation caused by coupling between high-gain tuned radio amplifier stages. These shields were often form-fitting and grounded by a finger or fingers attached to the chassis. Removal of the shields might result in a howler.

When metal-envelopes replaced glass, the envelope was connected to a base pin for grounding. These pins were hollow because their centers did nothing at r-f. All r-f energy is confined to the surface by skin effect.

Billions of shielded tubes have been manufactured. Every one is a testament to skin effect. If r-f could penetrate such a shield, equipment would have to be very large to provide the necessary isolation. All shielding depends on skin effect. If shields conducted r-f directly through as if it were d-c, they would not work.

When Roger`s "skin effect" experiment fails, it is a failure of the experiment. It is not a failure of skin effect.

Dear Les and Clair,

On some bands it might help. On other bands it might not.

Try it ? You could have an answer long before you can pass all the other antenna details, plus ground connection, plus tuner details, to the experts on this newsgroup, plus the thinking time. ;o)

You could arrange to switch from one configuation to the other.

Maybe a bit, but not too much. The antenna was pretty low to the
ground though.

If it was up in a flat-top configuration, then it should
> have performed quite nicely on 10m at relatively low angles.

It should normally. I think half the problem was ours wasn't really
too high.
And I'm sure it did have a bit of a V to it. I usually tie off to
trees, etc, and rarely are the ends as high as the apex.
>

It's sure worth a shot if the radio doesn't have the image problems
from the strong HF signals. This may be a quirk to the 706. Actually
here, I have 80/40/20 dipoles up parallel, and the match on 6m is
very good as is. But the images killed me. It's pretty clean with the
yagi.
>
> Now, we need 6 to open up!

It has a bit lately, but I haven't had much time to hover over the radio. I sometimes catch the east coast coming in in the late afternoons. MK

Reg,
would you start the loop directly from the terminal at the antenna
tuner, or would you have a feed of some kind to a split and loop from there?

Hi Guys...

I am currently running a Van Gordon Shorty All Bander Dipole. That I use for 10-80 meters. I realize this is a not so good antenna now... also running a 4:1 Balun, I know, it was my first attempt at a Antenna for H.F. I operate alot of 75 meters. and I was eyeballing the International Antenna Company's Double Bazooka for 80/75 meters. and also one of these for 40 meters. can't quite do 160 with one of those... not enough real estate here... I have a 40 ft tower. and could hang something from it... Anyone used one of these? and what kind of results? I use SSB portion of band, can I just hang and forget? I use a MFJ 989C tuner. Please, any feedback would be Welcomed. Remove the NO SPAM from e-mail address to reply via e-mail.

Cross-posted to: rec.radio.amateur.antenna,rec.radio.shortwave,rec.radio.amateur.misc,sci.electronics.basics,sci.electronics.misc

Hi,
I'm trying to get the first stage of a transistor emitter to oscillate.
I'm sure I've correctly built the circuit and I soldered the piecfeces as
close to the PCB as possible. I'm using a quartz along with an LC section
to create the carrier frequency and a varicap to modulate. These pieces are
connected between base and collector. The collector is attached to the primary
o f transformer. The kit's article suggests that I play with the variable
capacitor of the LC section and/or the height of the metallic
core of the transformer (which screws into a plastic cylinder). This
circuit is powered on 12 V. The only time the quartz oscillates is when
my finger or a screwdriver is touching the variable capacitor's screw head
(seems to be serving as an antenna). What can I do to make this stage
oscillate correctly? Are there any good books or references which talk about
troubleshooting problems like these? I'm a neophyte to this elusive world
of unseen EM waves.
Thanks,
Gabriel

Les,

I would be willing to challenge you for the worst possible QTH award. I am in a ground floor 2 level apartment facing west with absolutely no propagation to the east. On top of that, the landlords have an absolutely zero tolerance for outdoor antennas, I even had to take my satellite dish down. I am in Canada, no FCC here. I tried a dipole on the second floor, but a constant S9 noise level makes that impossible. The power transformer for the entire building is located underground just in front of the apartment beside me. I tried a loop antenna outside but even that is hard to hide. And to top it all off, my neighbours have one of them little chihuahua dogs that somehow knows when I am out in the yard trying to hide my antenna. It sits at their patio window barking like an alarm going off. So I have resorted to a 30' long err short wire out in the hedges at a whopping height of 5' above ground. I just thank god for psk modes where weak signal is king!

Any challengers??

Max

>Move this one step further and build the fixed tuner at the antenna and skip the line loss due to SWR.

Conjugate (conjugal hehehe) match proves loss is very small on 160m, with a tuner far from antenna even with high SWR. Thus the advise of putting the tuner at the antenna to skip the loss is not significant.

5178. Does the MFJ-16010 Work Well?

Newsgroup: rec.radio.amateur.antenna

>Best regards, Richard Harrison, KB5WZI

Hi All,

As a common consideration in matters of wavelength, it has been long observed that dimensions of less than 10% wavelength (10M) between points offer very little differential to create a current flow. Here, at somewhere around 3% (less than 2ï¿½) best case at the very highest frequency, the potential, for all practical purposes is the same everywhere on BOTH sides of the disk. Now, if we rummage around the HF basement, there is no way this disk would offer anything but nuisance.

This goes to the nature of wavelength and the prospects of measurements being swamped by the huge dimensions of the excitation wavelength. It is extremely difficult to find this precision such that you could demonstrate the disk even existed. Brainstorming such considerations should precede any testing - does what you are setting out to do make sense in the first place? The paragraph above should have been considered first.

This is a cautionary tale about measurement and the challenge of established theory. If you cannot pursue the negative example of your speculations - you have done nothing at all (the common, prostituted ethic of fractal antenna science). Making someone else do this undercuts the authority of your statements. The point missed through that shortfall of examination was that everything described (but the premise) was unexceptional.

Roger did his work in earnest and due diligence (except for the trivial capacitor insertion) and it took a while to connect succinctly to what foiled his premise. The measure of RF is exceedingly difficult and offering your credentials in the form of quality instrumentation does not make an argument (in fact, it negated it). Roger's data is exceptionally good and speaks volumes about the abilities of his Autek Model VA-1 RF Vector Analyst. This alone

answers the issues of how much the experimenter pollutes his measurement - practically none (not a simple feat). However, having said that, if you cannot quantify this, you really don't know anything. Basically, ALL the data reveals both the expected inductance of the leads, and the resistance of the resistor to within 10 or 20% tracking over the entire frequency range offered for consideration.

The reason that the neutral wire should not be used as a safety ground is because it DOES carry
current and there can be a difference in potential between ground and the neutral wire at any
particular location in the house. Voltage drop in the neutral wire from a load on the circuit.
While this voltage drop may be small in normal operation, it could become very high if there is a
poor connection between your location and the service panel. This voltage would come from
some load connected further down the line.

If the neutral line opened completely between your location and the service panel you could see
the full voltage from a load being turned on at some point further down the line from you. If you
had the neutral wired as the safety ground then the appliance would be at the full line voltage!
That is the reason for the separate safety ground.

There is one exception to this. Electric stoves. They use only 3 wires and do use the neutral as
the safety ground. All the elements are 220 volts so normally no current flows in the neutral line.
But there are sometimes 120 volt timers or outlets on the stove so then the neutral line would
carry some current. But the line to the stove must be a dedicated line directly from the service
panel. It must not be connected to anything but the stove. This is how they (NEC) justify this
setup. I think now though that a 4 wire circuit is now being used with

a separate safety ground.

Some hams wire their amplifiers to 240 volt circuits with 3 prong air conditioner plugs. That
circuit is two hot lines and a safety ground (at least it should be) . No neutral. This is fine if the
amplifier has no 120 volt connections inside. Sometimes a 120 volt blower is connected from
one side of the f240 to the center tap of the transformer primary in the amp. The transformer
acts as an auto transformer to run the blower. Again this is fine. But if there is any 120 volt
connection, then you must use a 4 wire circuit with a separate neutral wire to carry the 120 volt
load. You don't want the safety ground to carry any current.

The only reason that your furnace would not have a safety ground is if it has the power run to it
in metal conduit that is grounded. That would provide the ground. Otherwise it should have a
ground. If the inspector passed it he did not know what he was looking for. Not uncommon.

GFI breakers do not require a ground connection to work. They operate if they see a difference
in current between the hot and neutral lines. There must be the same amount of current in the
neutral line as there is in the hot line. If not that indicates there is leakage somewhere and the
breaker trips.

Double insulated appliances like coffee makers only have a two wire plug. Both sides are
insulated from ground and no separate safety ground wire is used.

Anything with a 3 prong plug requires a separate 3rd wire safety ground. Don't use the neutral
as a safety ground! That is worse than no ground at all.

Yes the NEC says that a safety ground must not carry ANY current. That is the difference
between the safety ground and the neutral wire. The neutral wire is always carrying current
equal to the hot wire.

The reason that the neutral wire should not be used as a safety ground is because it DOES carry
current and there can be a difference in potential between ground and the neutral wire at any
particular location in the house. Voltage drop in the neutral wire from a load on the circuit.

"Inpenetrable Metal Plate Experiment".

Skeptics abound as a result of learning d-c electricity before a-c
electricity. "Skin-effect" is incontrovertible.

I`ve been at sea with radios and installed radios on ships and boats. It
is a fact that a radio below the waterline but inside the vessel may
have a ground connection inside the hull but also below the waterline.
No r-f can take a short path through the hull to the water.

The ground path for the h-f antenna circuit must be up the inside of the
hull, through some exit hole, and down the outside of the hull to the
water surface.

Gary Schafer, K4FMX wrote:
"Don`t use the neutral as a safety ground! That is worse than no ground at all."

I agree that a separate safety ground is required. I disagree that the neutral is worse than no ground at all, so long as it remains intact.

5% is the usual maximum voltage drop allowed in site wiring. In the 120/240-volt circuit only the unbalanced current flows in the neutral, and its maximum is limited by the 120-volt breakers.

6 volts is 5% drop and the most that should ever appear between the neutral at an outlet and the breaker-box ground. Maximum neutral current occurs when all the load is on only one of the 120-volt circuits and the other half of the 240-volt circuit has no load. 6 volts is unlikely to hurt anyone and certainly not worse than no ground at all. In fact, maximum volts dropped in the neutral is likely only 3 volts because the 5% specification includes the drop in both wires of the 120-volt circuit, one of which is that same neutral wire. That voltage is almost trivial. It is certainluy not worse than no ground at all.

A friend recently asked me what to do? A new range had been delivered and the old model was removed by the vendor of the new range. He only had 3 wires to his receptacle and the new range needed 4. I told him to strap his neutral wire in the new range to the safety wire, just as it had been in the old range. Then to be safe, run a green wire to a cold water pipe in his kitchen to ground the range. He had already decided he would not run a safety wire to his breaker-box. The power company here requires a cold-water pipe ground for its electric service in addition to a ground rod where metal water piping is available. The friend followed my advice. His range works as expected and he hasn`t been shocked yet. I told him I would only verbally advise him and deny I had ever advised him if interrogated, Did he understand?

That`s why in olden times the neutral connection was made to the frame of your electric range.

Best regards, Richard Harrison, KB5WZI

StarGazer wrote:
> Why is 5/16 wavelength such a magically length?

Not magical, just convenient. A 1/4WL monopole has a feedpoint impedance of about 35+j0 ohms. A 5/16WL monopole has a feedpoint impedance of about 50+j80 ohms. For a perfect 50 ohm match, use a series cap with a reactance of -j80 ohms. But 35 ohms is an acceptable feedpoint impedance without an antenna tuner.

> What is a doorknob cap and where do I get one?

Doorknob caps are good for high power. But a simple air-variable cap may be more convenient because it is adjustable. Mica caps also work for relatively low power.

I've also seen many examples in the course of designing and using high speed TDR equipment. With that equipment, the path of current along one surface of something like a large PC board conductor and around the edge to the other side is obvious. With the TDR, the X axis of the display represents a distance from the source. You can put your finger on the conductor at various places and see the disturbance on the display that corresponds to the distance your finger is from the source. Then you can put your finger on the other side of the conductor at the same distance, and see no disturbance at all. The place on the display that you see the disturbance corresponds to the distance over one surface, around the edge, and back along the other surface. You can also see the current "soak in" to the conductor -- it gives a very distinctive, and calculable, shape to the step response as the effective resistance decreases with time. This is the time domain equivalent of the skin depth increasing with decreasing frequency (increasing time). Unfortunately, this sort of equipment isn't available to the average amateur, and to see the effects, the system has to be able to resolve distances shorter than the time required for the current to penetrate very deeply. If anyone does have access to high speed TDR equipment, though, a number of demonstrations that very clearly show skin effect can easily be set up.

It's 240 volt that I'm mainly concerned with. I don't use the neutral wire to ground 120v gear. From his post, I gathered that 240v gear needed a 4th wire for ground. I had never bothered with this in the past, as my neutral wire is well grounded. My amp is all 240v, including the blower. But from another e-mail I got, I was told it's not really legal to even do that any more. "3 wires for 240v use" I was curious about that mainly. I haven't read the NEC code. Don't have a copy...Don't know if it's on the net or not..

> The only reason that your furnace would not have a safety ground is if
> it has the power run to it
> in metal conduit that is grounded. That would provide the ground.
> Otherwise it should have a
> ground. If the inspector passed it he did not know what he was looking

The furnace is 240v. No conduit is required here if the wiring is indoors. We've rarely added a 4th ground wire to those, and so far, no one has ever said anything about it during inspections. A few have a wire run to the cold water pipes, but not too often. Most all I see are grounded only by the neutral. I'll have to look into that...I may should start adding a 4th ground wire...This is, it's not alway easy to come by a decent ground in most attics, unless water pipes are up there, and many pipes now are pvc. Most of the old homes with iron water pipes, it's pretty easy. Actually, now that I think about it, I'm getting my neutral for my 240v from the water pipe in the attic at this house. But we have all metal pipe, and it's grounded well.

Don't use the neutral
> as a safety ground! That is worse than no ground at all.

I don't except when running 240v. I'd never do that with a 120v device. From what I hear, I may have to quit doing that with 240v gear. MK

Remember though, if you use it as a loop, feed it with twin, not coax and if possible get yourself a tuner that is know as a, "Balanced ATU" (ones made by such companies has, "K.W" and "S.E.M")
You could make your own of course, if you are into the, 'Home-Brew' side of our hobby.
Failing having a balanced ATU you could try a 4-1 BalUn at the feed end of your loop.
Not has good as an ATU but may help in your position, good luck, Ken, G4KIR.

==========

You should have already done it by now. Are you waiting for me to fly over?
My passport, vaccinations and inocculations are all out of date. ;o)

Bring both ends of the loop just inside the shack (via window or hole in the wall) to the tuner terminals. The 60/50Hz power supply ground will be OK for all equipment. And you could have an additional ground connection to the domestic plumbing system. Prefer a cold water pipe as it is likely to take a shorter route to the true ground.

Whether anything makes any difference can always be checked by temporary disconnecting something and keeping an eye on the swr or S-meter. If it makes no difference then reconnect it anyway. Big alligator/crocodile clips are useful.

Nitpicking purists would insist on a choke balun at the loop/tuner junction. But as you won't have much idea what the feedpoint impedance is I would try it first without a balun and if it works don't fix it. Later on you may probably find a balun makes no difference except to shift a teeny extra performance from one one band to another. But don't let me deter you from further experiments. You may have a lucky strike.

But, you may find your peculiar inverted-L, lying on its side amid the neighbor's laundry, works as good as anything. In a few hours or days you will pleasantly learn much more than in weeks of poring through the 'literature'.

5199. substituting new toroids for noise gate circuit?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-17 10:20:24 UTC
From: AJ Sanderson <ajsand@nospam.com>
Message-ID: <am6vl6$7vm$1@nntp9.atl.mindspring.net>
Source record: 134490
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,sci.electronics.basics

I'd like to build a noise gate circuit for my HF receiver, to be located externally between the radio and antenna, but I'm not sure how to wind the toroids. The circuit I'm going to use (unless someone can suggest a better one for HF use) is at
http://www.lwca.org/library/articles/jtreed/gate/gate1b.htm

This uses two FT50-75 toroids and I understand I need to change these to FT50-43 for hf use (1.8- 30 Mhz). For 50 ohm input/ ouptut, how would I wind the toroids using 43's?

Thanks,
AJ

Thanks Reg,
seems like a job for an open wire feeder and the balun
terminals on the Howes CTU 30 tuner. more fiddling to come! Although at
the moment, just having a signal to play with is a novelty. Tripoli ATC on
11.300 USB clear as a bell last night. Using volmets as a guide to
performance, New York/Gander reasonable but St.Johns eludes me... next
target perhaps.

Remember the huge old transmitting mica caps with the threaded brass
connections? I still have several of the things. Somewhere. Used
mostly for plate blocking caps in big amps.

5204. Unusual half sloper -- second try

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-17 13:24:37 UTC
From: Bill Ogden <ogden@us.ibm.com>
Message-ID: <3D872D14.1DE3AA9E@us.ibm.com>
Source record: 134496

(I posted the following last week, with no response. Has anyone tried one of these?)

QST (some years ago) and the second Wire Antennas book briefly discuss a

wide-band 80 meter antenna, with two examples described. It consists of

a "half sloper" attached to a tower, with two more wires connected directly to the tower (at a lower point) and horizontally fanned out into a "V". The half-sloper is routed down between the the legs of the V. An almost flat SWR across 75/80 meters is shown.

In one of the examples the tower is 50', the half sloper (78' long) is attached at the 45' level, and the two V legs (each 53' long) are attached at the 13' level.

1. This antenna seems too good to be true ---- absolutely flat across the whole band and with reportedly excellent results. It was originally

in an April issue, and some April articles are too good to be true. Comments?

2. Little is said about how dimensions are calculated. I would like to use it on my little 40' tower (with a quad on top). I would attach the sloper at about the 30' level and the V at about 8'. Is this unreasonably small/low?

3. Has anyone tried a two-band version? It would be nice to connect a second sloper to the same feed point, but for 40 meters. Would the same

V section work for both?

I realize that most of the effective radiation is from the tower and ground/radials are important. (I also realize that a dipole at 60' (or higher), or an inverted V might be a better answer, but I do not have that option.)

"Then you can put your finger on the other side of the conductor at the same distance and see no disturbance at all."

That is a great demonstration of skin effect shielding by a conductor, using time domain reflectometry.

Another example that many can relate to is the coax run through the car trunk. Any imaginable cargo can be placed in the trunk in close proximity to the coax and radio operation is completely unaffected.

Roger, W7WKB wrote:
"Without some indication of the difference between the circuit with the disk, and the circuit without the disk, the conclusion must be reached that skin effect shielding does not occur for the thickness of disk material and frequency range tested."

It would seem that the original ground-plane antenna is in a way similar to Roger`s experiment. It was a 1/4-wave vertical in the center of a 1/2-wave diameter horizontal disk.

ON4UN`s "Low-Band DXing" has Fig 9-40 on page 9-31 which gives gain versus the radius of the disk. Full performance requires a disk RADIUS of at least 2 wavelengths!

As Richard Clark observed, Roger`s disk is much too small.

With this experiment, we could not expect to find any difference between the two circuits at the lowest frequencies due to skin effect shielding because the frequency is so low that skin effect is not well developed. At the lowest frequencies, current should pass easily through the disk.

At 30 MHz however, skin effect will cause the currents parallel to the disk surface to be concentrated near the surface. But what about currents normal to the surface? The contention is made that skin effect will prevent currents normal to the surface in which case the current would have to follow a surface path. The surface path is longer by two times the radius of the disk so the time of wave travel would be longer by the increased distance divided by the velocity of the wave.

A rough circuit equivalent would be a transmission line stub as long as the disk radius. But this is worse than a rough equivalent because skin effect is proclaimed to be so effective that even capacity effects can not penetrate the skin effect shield. Therefore the capacity that exists between the sides of a transmission line stub would not exist across the skin effect shield.

We are left with a skin effect equivalent circuit that is like a stub transmission line but without capacity between the sides of the stub. But without knowing the capacity between the sides of the transmission line stub, we can not know what the transmission line impedance will be, nor the effective inductance created.

So the bottom line is that the skin effect shield theory predicts that current will not pass through the disk in this type of circuit at 30 MHz, but makes no prediction about what measurable effects can be expected due to the detour that the current must take.

This brings us to the heart of the problem. Predictability. A designer of shielding when working at low frequencies (1 MHz for example) can not depend upon skin effect to accomplish his task because the weight/thickness of the materials he is likely to use would be too costly. This designer would have to depend upon good current balance to achieve good shielding. As the design frequency increases, skin effect becomes more effective, so the designer has less need to worry about circuit and current balance. Perhaps skin effect even becomes extremely effective at some frequency so that circuit balance and current balance is not a factor at all, but at what frequencies does this occur? So far, there is no evidence that the design requirements for shielding at 30 MHz are any different than at 1 MHz because skin effect shielding has "taken hold" at 30 MHz. Current balance is the key to successful shielding at both frequencies.

The antenna designer has a question about the fold around current on the shield side of the coaxial transmission line. Apparently there is no effective fold around current at 1 MHz because the skin effect shield is not adequately developed at that frequency. But there is a problem at 30 MHz because skin effect is well developed at this frequency. True? Not if you consider the results of the two experiments.

The two experiments were both were designed to demonstrate skin effect shielding. If either experiment had shown a change that could be attributed to skin effect shielding, we would be on the path of predicting the measurements that should be expected when skin effect shielding is present. The results so far have not shown any effects that can be attributed to a skin effect shield.

Just thought some of you might be interested:
It seems the last "tree spank" was a doozy! Actually, I had forgotten that it wasn't a "tree spank". One particular morning I had spanked an extremely low train underpass all the way across. It was loaded full of steel girders.
It didn't connect at first, why on some occasions the "stingers" would only go down part way and then stop. On other days, they would go all the way down.
It looks as if I've broken the inductor cores, and pieces of carbon have been clogging the stinger hole. Pieces of carbon are now coming out of the stinger hole.
I think I'd better mount these things a little lower next time.

Mike

Hi Mark,

If the equipment is 240 volt only and doesn't use a neutral (like a window air conditioner) then it
is ok to use 3 wires. They will be 2 hot and safety ground. No neutral involved.

The 240 volt furnace ground should be to the safety ground, not the neutral. But if it is a
dedicated line from the service panel then neutral or safety ground of course are the same. As
long as the neutral wire doesn't get used as a neutral and carry any current.

Same for your amp. If it is all 240 volt then no neutral is required. Only the safety ground. Some
people have 240 volt amps that do have also 120 volt circuits in them and use the chassis as the
neutral and ground. This is dangerous if you should lose the ground. Then the chassis is hot with
120 volts. In this case 4 wires are needed and the neutral would not be connected to the
chassis.

Using the neutral as a ground is dangerous as lines are usually routed through multiple outlets.
The chances of the neutral becoming open are greater because of all the connections and the
possibility of someone making poor connections/ repairs at a junction.

I had a house several years ago that had most outlets in the house with the wires on the screw
terminals but the screws never even turned down. I am not talking about not being tight, they
were never even started in!

In a situation like the above if the neutral was used as a safety ground on some apparatus and
one of those neutral connections between the service panel and the apparatus were open, the
apparatus chassis would be at full line voltage through its internal circuit. Or it could become hot
if some other appliance down line were turned on.

The situation with an electric stove requires a dedicated line to use the neutral as ground. A little
safer than doing it on a multiple outlet circuit. But even that is changing to 4 wire requirement.

As posted earlier, the skin depth in copper is only 2 thousandths of an inch at 1MHz. It doesnt run much deeper in aluminum either.

You must have seen the thin aluminum cans used to shield coils in medium wave broadcast receivers. These are also effective at the lowest intermediate frequencies, say 50 KHz. They are grounded so that they don`t become just a plate in a series-connected coupling capacitor.

I have a 5' Curtis Martin rooftop tower, which is WELL mounted.
(Put it up when re-doing the roof - removed the sheathing
and put in "sandwiches" of 3 2x8's on edge between the rafters
and 2 8' 2x8 spanning the 4 "sandwiches" and the rafters.
The tower legs are lagged into the "sandwiches" with some
huge lag bolts. If the tower goes, the roof rafters
have to go.)

My question: How much above the top of the tower can
I install a 5 element 6 meter beam, without bending/
breaking the mast? I *assume* that I can put it right at
the top of 10' of 2" mast, with a 3 element tribander
halfway between the top and the thrust bearing. I
figure it is better to ask for advice BEFORE I screw it up.

Roger,
you should learn to take the comments of Roy, both Richards, et al
more to
heart. If you want anyone to take you seriously you'll have to develop an
analytical
description of what is taking place in your experiments based not on currents
alone,
but on field theory. This is a problem of physics. Good luck.

"I`m getting my neutral for my 240v from the water pipe in the attic in the house. But we have all metal pipe, and it`s grounded well."

Before HL&P switched on the power to Mark`s house, the city inspector had verified the solid meter ground to that cold water pipe. If the inspection slip was missing, HL&Ps inspector verified the grounds before supplying power. Mark`s neutral connection to the pipe is probably the best in the house. There`s an approved clamp at the meter end and no way will he melt the pipe or lose continuity until the pipe freezes ruining the contents of his house, and the plumber cuts out a piece of the pipe for replacement. That`s a time for extra care to avoid electrocution of the plunber in the attic.

Source record: 134516

Your mileage may very but I have been successful in using IMC Electrical Conduit as a mast. This is not the thin wall stuff but thick like pipe although not quite as thick as rigid conduit. I have used 10 feet of 1 1/4 inch from the rotor plate within my Rohn Top Section. So I'd sat it extends about 7-8 feet above the tube on top of the top section. Not much weather here in Oakland although we occasionally get some windy days. It's up at a total height of 30 feet. I've watched it when the wind was strong enough to really flex the TA-33 a bit but I was never able to see any deflection of the mast. I am confident enough that I am planning on extending it another ten feet or so with the same conduit. However, could be famous last words hihi. But you know if it doesn't come down in a storm it probably wasn't big enough or high enough to start with.

BTW I also use telescoping lengths of 10 foot IMC to make up my main mast for inverted vees. I use 1 1/4, 1, 3/4 mounted to the chimney atop my roof for a total height of about 46 feet. Not good enough for a beam but supports two vee's just fine. I fasten them at the telescope points with a threaded hole and a machine screw and it sure beats Rat Shack push ups and a whole lot cheaper.

5226. Re: safety ground and antenna ground - tie together and connect to ...

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-17 22:45:38 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D87B092.4080709@eznec.com>
Source record: 134424

My daughter's recently purchased older home had been professionally rewired, but someone had put in one obvious kluge since -- a power outlet strip wired in with about a mile of black tape. I went prepared with parts to redo it right -- ahem, that is, to advise my daughter how to do it right -- and discovered that the romex from the kluge went to a box that furnished power to a baseboard heater. The heater was 220 volts, 2 wire, with a safety ground, and that's all that was coming into the box from the service box. The romex going to the kluged outlet strip was connected between one leg of the 220 line (ok) and the safety ground (NOT ok!). The wire and outlet strip came out until there's time to do it right.

If you're going to fool with wiring, you absolutely should have at least a home-handyman book on wiring, learn the general principles, and follow the procedures exactly. If you're going to do anything very major, it pays to invest in a copy of the NEC**. I did some major wiring for an addition and replaced the service box some years ago -- all with permits and all inspected -- and found both kinds of book to be indispensible. NEC to give me the straight answers about what was ok and what wasn't, and the home-handyman book to show me the tricks I never would have discovered otherwise (like "expander rings" -- to increase the volume of an installed box so it meets the NEC requirement for minimum volume when you run additional wires into it).

Besides the safety issues, if you do non-code wiring you run the risk of the insurance company having a way to avoid paying if you ever have an electrical fire.

Roy Lewallen, W7EL

** Some latecomers or casual lurkers might be confused, since another NEC comes up on this newsgroup quite often. The one being referred to on this thread -- and anywhere else electrical wiring is discussed -- is the National Electrical Code, which most localities in the U.S. have adopted as the official code dictating electrical wiring standards. The other NEC (NEC-2, NEC-4) you see referenced on this newsgroup a lot is the Numerical Electromagnetics Code, a series of computer programs used for antenna analysis. The two aren't related.

5228. Mag mount for base application?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-17 23:17:58 UTC
From: haytirebl@aol.compost
Message-ID: <20020917191758.18884.00004057@mb-fz.aol.com>
Source record: 134518

Hi all,

I'm getting back into the hobby after several years off. I used to use a mag mount 2m as a base ant. but in the years of inactivity, have forgotten how to do the ground plane. At one time, I stuck it to an old cookie sheet and it seemed to work fine, however, I don't remember the size. Is there a formula for figuring base area needed to use this type ant. as a base? Any help would be greatly appreciated!

Thanks in advance
Tom KB0WYG

well i am sure you will get a wide range of opnions in here
but yes you can mount it above the HF beam just mount it about 5-6 feet above the HF beam and everything will be fine
if you mount it vertically make it 5-6 feet to the tip of the elements on the bottom
good luck

(Many web sites deleted.)

Thank you for the many crackpot websites. The attempts to justify the CFA based on the Poynting vector are truly impressive in number. The Poynting vector, however, is beside the 'poynt', and used wrongly in any event. Those who try to use it to explain a natural phenomenon (the radiation of a CFA antenna) first have to demonstrate that the phenomenon exists. No one has been able to do this, nor even to present a demonstration of the theory that has any more use for designing antennas than the Book of Mormon.

Much of what you are asking depends on the weather and how long you want the installation to last.
First, I would replace the lag bolts with machine bolts that are long enough to go all the way through the "rafters", put large washers, and double nuts to really secure the tower.
Next, I would use 1/4" wall seamless Chromoly steel 2" OD tubing. You can get it galvanized, or you can clean it very well and "paint" it with Cold Galvanizing material.
If your rotor and antennae work with 2" OD mast, you will be happier in the long run with a much stronger material.

Source record: 134426
Cross-posted to: rec.radio.amateur.antenna,alt.rv

Extended warranties, whether on your MH or a $15 wristwatch, are literally and precisely insurance policies, with the prices set so the sellers make a profit. It's called capitalism, and it's a valid means of making a living. By the very definition of extended warranties, the average buyer loses money. If he didn't, the company would go broke.

If you break things more often than the average bear, by enough margin to offset the insurance company's profit margin, you win ... unless the seller goes out of business first.

If you're too poor to buy your own new engine when some engine part SPECIFICALLY LISTED IN YOUR EXTENDED WARRANTY POLICY fails DESPITE FLAWLESS MAINTENANCE, you may want an ext warranty. If, OTOH, you can afford to fix that engine, you will come out ahead in the long term if you never buy another extended warranty on anything you buy.

It's simple statistics, and it's exactly like walking into a gambling casino. The house ALWAYS wins in the long run, or it folds.

Do you feel lucky, punk? ;-)

Well, vertical is about 21 feet in length (height?), and I have a small number of ground radials (yes, ground radials, not a counterpoise) of various lengths (10 to 25 feet, bonded to chain-link fence which runs on either side of yard). Frequencies are the AmateurHF bands.

I was hoping for just a generalization, really, if possible.

Probably the best advice of the day!

The only problem is that I got started down this path because some experiments I was doing a couple of years ago just weren't working when I tried to apply the skin effect shield idea. When I made the hard decision to abandon skin effect, the work came together very quickly. No big deal but frustrating when it appears the book is giving you wrong information.

So when I start testing to see how detectable skin effect is, I detect nothing. All I get for advice is skin effect works, and no test available to a ham can detect it. Maybe we can't detect it because it is not effective in the way we are told at HF. No one will even give an impedance number that the disk should introduce into the test circuits.

So, with all due respect, I think skin effect shielding at HF is a ham radio myth. Sorry, the evidence just points in that direction.

Source record: 134430

Tom:
For years I recommended cold galvanizing as a repair/replacement for the hot dipped zinc which is on there now. However, after considerable discussion and some experiments, I have come to the conclusion that cold galvanizing is the expensive way to do it. To prevent future deterioration, the requirement is to apply a continuous unbroken film of protection on the surface which will keep moisture away from the steel. Latex paint won't do this nearly as well as a good old alkyd enamel, applied carefully to a clean surface with all the rust removed. Rust is porous enough to contain enough moisture to keep causing further trouble. And, before the purists complain, it is the oxygen dissolved in the moisture which is the actual problem, but moisture is a sort of catalyst. But be extremely conscientious about application, and leave no gaps, scratches or other uncovered areas.

Has anyone put on some serious mileage using a Webster Bandspanner antenna and a Magnetic Mount?

I have a heavy-duty 3-pad magnetic mount that *looks* like it will stay stuck to the car at highway speeds / winds with a Bandspanner attached, but just haven't found the guts to try it yet.

Perhaps another way of asking the question is, "what are some 'heavy' antennas you've been successful with using a 3-magnet mount? ... what are the horror stories?" Surely these magnetic mounts can handle more than a Ham-stick!

Thanks,
Jeff

Not much more. A 3-magnet mount won't handle a 40m Hustler. The problem
is meeting 18-wheelers on two-lane roads. The antenna gets hit essentially
by swirling 150mph winds. The 4-magnet mount might handle a 40m Hustler.

Gabriel Horner wrote:
"I`m trying to get the first stage of a transistor emitter to
oscillate."

All that is required for oscillation is a gain greater than one and positive feedback of a fraction just equal the recriprocal of the stage gain.

In the Feb. 1971 issue of QST was an oscillator which seems similar to the one described by Gabriel. The article was entitled "Quick and Easy Portable / Mobile Reception" in which a superregenerative detector base modulated a transistor crystal-controlled oscillator for reception by an AM radio. It was written by Doug DeMaw.

The oscillator used an NPN transistor and was powered by a 12-volt supply.

The oscillator load was a permeability-tuned circuit. The crystal was connected between collector and base of a common-emitter circuit.

The forward-bias voltage divider cobsisted of 68K and 10K resistors putting about 1.5 volts on the base. The emitter resistor was 470 ohms so that the 0.9 volts across would result in about 2ma through the resistor and thus through the transistor, before oscillation starts.

The emitter resistor is bypassed with a 0.1 microfarad capacitor so that the gain is controlled by the ratio of the load impedance to the inherent emitter resistance of 26 / 2ma, or 13 ohms. The 0.1 microfarad capacitance is adequate for the 550 KHz to 1600 KHz frequency range, and 470 ohms, as a bypass.

This circuit almost has to oscillate if the collector is tuned on or near the proper side of the crystal resonant frequency. In fact, it should oscillate with a 2.2K resistor replacing the tuned circuit. Will it tune to the desired frequency?

The transistor with a 2ma collector current and a 2.2K load should have a gain of about 150, so not much energy needs to be fed back from the output to the input through the crystal to cause oscillation (less than 1%).

Almost any any good electronics text covers crystal oscillators. Amateur publications such as W1FB`s Design Notebook, Solid State For The Radio Amateur, or The ARRL Radio Handbook should illuminate oscillators.

Gabriel has a diagram of the oscillator stage he is trying to get working. First, carefully check to see that every part is correctly

connected in its place.

There are only a few parts in the oscillator so it isn`t too hard to check parts, though this is an uninspired method of troubleshooting.

I would check voltage across the emitter resistor to see if the transistor is turned on, if there is an emitter resistor. Then I might short the base to the emitter to see if I could turn the transistor off. If the transistor turns on and off, it`s good, 99&44/100% of the time. Do you have a metered power supply to monitor voltage and current?

You need a receiver tuned to the frequency of the crystal (or oscillator frequency if it`s an overtone circuit) to detect oscillations, or use some other detector of your choice, a GDO or whatever.

If the circuit isn`t oscillating, see if it works as an amplifier. It should and maybe the crystal doesn`t work. Replace the coil in your GDO with the crystal and dial out most of the tuning capacitance to find the point the crystal breaks into oscillation. If the crystal oscillates it`s probably good. Find its frequency roughly with your receiver or precisely with your counter.

There are too many troubleshooting techniques to report here even if I knew them all which I don`t. This posting is already far too long, so, GOOD LUCK!

Best regards, Richard Harrison, KB5WZI

I began through the list, figuring that there surely isn't a single decent quantitative measurement in the lot. But was I pleasantly surprised! The third of fourth one contained a link to some decent measurements, done by a college student who took pains to control feedline radiation and make good measurements relative to a reference antenna. You can find the results at http://www.ee.surrey.ac.uk/Personal/D.Jefferies/ref.html. Interesting, and much more convincing than the likes of "produced the odd QSO on 1.8 MHz". And pretty much in line with the CFA model that was measured and reported on by Trainotti in September 2001 IEEE Trans. on Broadcasting.

If anyone else finds some actual and decent measurements buried in this list or elsewhere, please post the URL. An objective picture of the actual performance of the CFA and EH antennas is slowly emerging, mixed among the great piles of propaganda, bafflegab, and religious experiences people are having with them.

Zinc Chromate. Now outlawed for aircraft use...at least in my neck of the woods. Fairly cheap now as millions of gallons are left undisposed of. Most ZCh is a nice shade of cat puke green but will allow just about any other type of paint to adhere to it. If you know anyone in the railroad industry, throw a bit of Dupont Imeron over the ZCh. That should last a few years.

Cross-posted to: rec.radio.shortwave,rec.radio.amateur.antenna,rec.radio.swap

MFJ-1026 Phaser for sale. This is the phasing unit with the internal whip antenna and internal pre-amp for the auxiliary antenna (or noise) input. I have found this internal amp to be very helpful when using a less than optimum
noise antenna.

The unit will be packaged in its original carton and it includes the original vertical whip antenna. It also comes with the original manual.

This unit has less than 3 hours of use on it and works per specifications. I have used it for BCBDX'ing, nulling out pest stations to reveal stations underneath or on adjacent frequencies that I would have otherwise not been able to hear. It also work on electrical noise from computer monitors, and televisions, etc.

The unit has been modified so it works in the long wave and medium wave (BCB) frequencies. The modifications have removed the hi-pass filters but the unit does not have the input main/aux antenna swap switch.

There is alot of information (including modification instructions) on this unit at:

http://www.hard-core-dx.com

I have pictures of the unit that I can send to anyone that requests them.

The cost is $130.00 plus the shipping cost from zip code 92008 (near San Diego, CA.). I prefer mondy order, but personal check is OK, but personal check must clear prior to shipping unit.

Ask for the pictures, you will see the unit looks brand new.

You can verify my e-bay rating by looking at diamond_jim.

> current.

No, the neutral and equipment grounding conductor are NOT the same.
A 240 volt circuit may, or may not, have a neutral - depending on whether
120 volts is also desired at the equipment.

A 220/240 volt service, with neutral, will have four wires in the cable.
There will be a black (one leg of the 240), a usually red (the other hot
leg), a white (common) and a green or bare (equipment grounding conductor).

"Neutral" is actually a poor term, as it is not that in many instances.
"Common conductor" is the term used in the industry - and the conductor
often carries current. The equipment ground should never have any current
flowing on it.

> Same for your amp. If it is all 240 volt then no neutral is required.
> Only the safety ground. Some
> people have 240 volt amps that do have also 120 volt circuits in them
> and use the chassis as the

It is also illegal - at least, in the US. It is dangerous, even if you
don't lose the ground.

> Then the chassis is hot with
> 120 volts. In this case 4 wires are needed and the neutral would not
> be connected to the

All this shows is that your experiments were faulty.

It is trivial to show that there is such a beast as skin effect. Every
piece of coax in an RF circuit demonstrates that phenomenon.

So do the thin metal shield cans for RF/IF transformers and tubes in
many old radios. Even transistorized radios contain such shielded
components.

wrote:

>Certainly this disk experiment indicates that the fields can penetrate the
>walls.

No, it doesn't. The disk experiment is not topologically equivalent to
a shielded enclosure. The connections to the disk are both on the
outer surface. The disk has only one conducting surface (exterior),
not two (interior and exterior).

Imagine an ant crawling from one disk terminal to the other. It can
follow the radius to the rim of the disk, cross over to the opposite
side, and proceed down the radius to the other terminal. No
teleportation is necessary to move from one side of the disk to the
other, the ant just crawls over the edge.

Now imagine the ant trapped inside a continuous shielded enclosure (a
hollow, sealed metal box). No matter where it crawls, it never gets
out. Unless, of course, the box has a hole in it big enough for the
ant to go through...which is analogous to having too large a void in
your shield.

This analogy may seem a bit childish, but it does represent how skin
effect and shielding work. The current will flow radially, out and
back. There is negligible current axially through the conductor; in
fact, you could hollow out the disk into two thin plates connected
only at their rims and not know the difference (until you check RF
resistance at LOW frequencies, where skin effect isn't dominant).

Good work. I assume you'll publish your results in one of the scientific journals. It'll make you famous.

But don't stop there. Try this experiment:

Charge a 1000 uF capacitor to 10 volts. The energy in this capacitor can be shown (by discharging it into a resistor sitting in an insulated container of water and measuring the resulting temperature rise of the water) to be equal to (C*V^2)/2. Then connect the capacitor to another, completely discharged 1000uF capacitor. Use a direct, very low resistance connection. You'll find that you end up with 5 volts on each capacitor. Now, the energy you had to begin with = (.001 * 10^2)/2 = 0.05 joules. The energy you have after connecting the second capacitor = (.001 * 5^2)/2 * 2 = 0.025 joules, half the amount of energy you started with. (You can confirm this by the same method as you did for the single capacitor.) You've now proven with a simple experiment that the law of conservation of energy is a ham radio myth, too.

Since the law of conservation of energy is a myth, there's no reason you can't find a way to reverse the process. Which can be confirmed with a simple experiment. . .

Your variable capacitor may be in backwards. Any crystal oscillator will
oscillate only if the L and C are adjustd correctly. So you should play
around with only one at a time.

For two horizontal beams, a good minimum distance is half the stacking distance that the manufacturer quotes for a pair of the 6m beams.

This is based on keeping the HF antenna out of the capture area of the 6m antenna. There's a more detailed explanation on my web site.

OK, let's all take the bait:

What was the experiment?

What did you expect it to show?

Why do you think it failed?

If you provide all the necessary information, then there *will* be an
explanation that doesn't involve abandoning the skin effect.

It should work but on forty you may have to reverse the input and output..
as the 30 ft wire will show a low impedence at that frequency. you'd be
better off if you could make they antenna about 66 ft.

Hello all,

Please help. I am trying to build an antenna made of a coil to receive the signal from a 25KHz. transmitter. I would like to have the coil to be as small as possible and to be able to receive the signal within 3 meter distance. I have the following question:

a- What type of core material should I use for the inductor?

b- Is wire guage important?

Any other factor should I be concern?

Thanks for all your help in advance,
John.

Yep. If you were running 100 watts, you were putting out the same signal as you would running a half watt to a full sized dipole. The QRO crowd just has no idea how much you can work with a half watt to a dipole. And on 20 meters, especially at the top of the sunspot cycle, that includes a lot of DX.

Roger wrote:
"No one will even give me an impedance number that the disk should introduce into the test circuit."

When skin effect is fully controlling conduction, materials have a "surface resistivity". "Ohms per square" express surface resistivity. The material may have an an area of a square inch or have an area of a square mile. It`s all the same.

Doubling the distance across such a surface conduction resistivity tends to double the resistance, BUT the effective width of the current path doubles too and the resistance total remains the same. The skin depth is a constant which we will specify only varies with frequency for a uniform material.

The surface resistivity of copper is about 0.000262 ohm / square at 1 MHz.

The resistance to r-f between points connected by a reasonably large copper sheet is 0.000262 ohm at 1 MHz. The distance between doesn`t count.

The resistance at 10 MHz is 3.16 times as great because the surface resistivity varies as the square root of the frequency.

This means that Roger`s copper disk offers little isolation from its resistance at 1MHz or at 27MHz.

Best regards, Richard Harrison, KB5WZI

wrote:

|Good work. I assume you'll publish your results in one of the scientific
|journals. It'll make you famous.

Heh heh.
|
|But don't stop there. Try this experiment:
|
|Charge a 1000 uF capacitor to 10 volts. The energy in this capacitor can
|be shown (by discharging it into a resistor sitting in an insulated
|container of water and measuring the resulting temperature rise of the
|water) to be equal to (C*V^2)/2. Then connect the capacitor to another,
|completely discharged 1000uF capacitor. Use a direct, very low
|resistance connection. You'll find that you end up with 5 volts on each
|capacitor. Now, the energy you had to begin with = (.001 * 10^2)/2 =
|0.05 joules. The energy you have after connecting the second capacitor =
|(.001 * 5^2)/2 * 2 = 0.025 joules, half the amount of energy you started
|with. (You can confirm this by the same method as you did for the single
|capacitor.) You've now proven with a simple experiment that the law of
|conservation of energy is a ham radio myth, too.
|
|Since the law of conservation of energy is a myth, there's no reason you
|can't find a way to reverse the process. Which can be confirmed with a
|simple experiment. . .

Why didn't I think of this! I going to put a resistor in a container
of hot water and charge a capacitor with it. <g> Solar-powered radio
here I come.

Source record: 134455

Roger wrote:
"If you don`t have time or the ability to look at the web page, I can tell you thet the metal disk did not lower the resonant frequency of the antenna."

CAN replied:
"Move the metal disks to the ends of the antenna and it will lower the resonant frequency."

Yes. Capacitive hats work. Why would the disks not lower the resonant frequency by some slight amount near the drive point? The impedance there is much lower, but it is not zero. The disks don`t have much inductance, but they do have
some small capacitance.

Hi
..what does the word "works" mean?
sure we are not scientists but will be more useful to know
(waiting for a scientific test)
how many db is EH under a dipole or an other "well-known" antenna?
my "quick-test" say to me it's more then 10 db under a full size dipole;
did you compare your EH with other antennas?
ciao

jr127@web.com wrote:
>
> The site is back but when I went to it, it locked up my computer.

Probably not. Eham uses lots of nested tables, and Netscape 4.x has problems displaying the page. It takes a while for it to display, and during that time, the computer appears "locked up". You can wait, or you can use a newer version of Netscape, or use another browser. This is a long-standing problem with Netscape and large tables, and one of the reasons that they completely rewrote the rendering engine for Netscape6.

5269. Re: Tower mounted short vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-18 16:01:27 UTC
From: richardharrison@webtv.net
Message-ID: <13504-3D88A357-24@storefull-2312.public.lawson.webtv.net>
Source record: 134460

Kent, VE4KEH wrote:
"Well the vertical is about 21 feet in length (height?), and I have a small number of ground radials-----."

Ed Laport has worked out the radiation resistance versus electrical height for short vertical radiators. It occupies page 25 of "Radio Antenna Engineering". For a vertical with no capacitive loading:
2 deg,. 0.012 ohm
3 deg,. 0.027 ohm
4 deg,. 0.05 ohm
5 deg., 0.075 ohm
6 deg., 0.11 ohm
7 deg., 0.15 ohm
8 deg., 0.2 ohm
9 deg., 0.25 ohm
10 deg., 0.3 ohm
15 deg., 0.7 ohm
20 deg., 1.2 ohm
25 deg., 2 ohms
30 deg., 2.8 ohms
40 deg., 5 ohms
50 deg., 7.5 ohms
60 deg., 10 ohms

As total loss in connections, wires, tuner, the earth, etc. are in series with the radiation resistance, it is easy to see why longer is better.

> at what distance apart? THANKS

I have my homebrew 2M vertical beam mounted *directly on* the forward
boom of my CC A3S. I'm sure neither one really 'sees' the other.

As well, I have a horiz 3el CC 6M beam mounted 5 feet above the
tri-bander -- _with_ a horiz CC 215WB (13el 2M) mounted in between
those two.
It growed like Topsy...

I'm sure I could 'do it' better. I'm also sure I could get my
cholesterol lower and my weight down some, too.
I try to spend more time actually _on the air, operating_ , than
online, in the newsgroups, anguishing over why something 'won't work'.

Actually, I was thinking more in terms of charging the capacitor from a resistor in a container of room-temperature water. Then you could use the resulting ice for your margarita. But I guess you gotta walk before you can run. . .

You might be able to use a military surplus antenna since that frequency range is within the 225-400 MHz 'Military UHF' band. There are high gain antennas used for ground-based MilSatCom. There was even one for sale around here a few months ago.

I don't know about the particular frequency allocations in Mexico, but in the rest of North America you would certainly wouldn't want to continue with such a project unless you enjoy long boring conversations with men in black suits.

YMMV.

Unless it is an unusual situation you do not need an antenna tuner. If
there is enough swr that a tuner is needed on 2 meters and up , you will be
loosing a lot of power in the feedline.
Change or do some work on the antenna.

I painted my 70' Rohn 45 tower with mil-spec zinc chromate paint, very nasty stuff, and topcoated that with two layers of Rustoleum enamel. After thirty years up in a foul heavy industrial envoirnment the top two sections were shot but the rest of the sections in varying degrees were still in quite reusable shape. In fact five of 'em did go back up at another ham's antenna farm after I took the tower down and in many places the Rustoleum finish still looks fine.

I've come to the conclusion that there are two mechansims at work as far as the degradation of steel towers is concerned. One is the usual oxidation/rust. The other is mechanical abrasion caused by wind-borne particulate matter, i.e., a "sandblasting " effect. The evidence lies in the fact that, at least in my case, the damage was progessively worse from the bottom of the tower to the top. This cannot be explained by simple exposure to rain & humidity, those are constants from the bottom to the top of the tower. The top of the tower should have been in better shape if moisture was the culprit because the top should dry out faster than the bottom end but that was not the case. The wind speed gradient on a tower is such that the top end takes much higher average winds thus a lot more "sandblasting". That would explain the "damage gradient".

It strikes me that the primary factor in the selection of tower coatings should be abrasion resistance with oxidation resistance being a secondary consideration.

Hi, Roger,
you've got to make allowances for Roy's sense of humor - he's
an
engineer. You shouldn't be surprised at the reaction, though, since skin
effect

has been described in virtually every text on classical electromagnetics ever written. (That's
hyperbole in case anyone wants to make an issue of it. I haven't read every textbook on electromagnetics ever written.) The fact that you seem
to have found a case that has satisfied you that skin effect is an old wive's tale
just means that you have to do more study, experimentation, and thought. As I wrote before, good luck.

Tom Donaly, KA6RUH

(P.S. When you do experiments that you make up yourself, always expect to be fooled, and never, never expect them to convince anyone of the conclusions you derive from them who doesn't fully agree with you, beforehand.)

I would like to build an antenna and thought a vertical would be better than a dipole since I'm in a fairly remote location. I'm thinking of building a 1/4-wave antenna for 80M. If I feed this antenna with balanced line using choke baluns and a tuner would this work well for 20M and 40M as well?

I want to hang the antenna from a tree and was wondering if a dipole would be better than my planned vertical because it has more wire up high?

Take any antenna tuner intended for the 20m band and divide both the inductances and capacitances by 10 :-).

But seriously, why do you want to use an antenna tuner on VHF/UHF bands ?

While the use of an antenna tuner on HF may be justified due to the relative width of the bands e.g. 13 % for the 75/80 m band and the extremely high length to width ratio (and hence narrow bandwidth) of wire antennas. In this case the antenna tuner tunes both the antenna _and_ feedline into resonance.

On VHF/UHF the relative bandwidth is smaller and by using thicker tubing and folded dipoles, the antenna bandwidth itself can be made sufficiently wide. Since the feed line losses are considerable at VHF/UHF, trying to resonate the feedline _and_ the antenna with an antenna tuner down at the transmitter, even larger losses will occur.

If you really need an antenna tuner, which I doubt, it should be mounted at the antenna and be remotely controlled, unless you want to climb the tower each time it needs to be readjusted. By this arrangement only the antenna is tuned and the feedline is not resonated, thus keeping the feedline losses down.

Some years ago I saw a review of such a tuner (probably in RadCom). I don't think many were sold, though, and it wasn't in production for long. It sticks in my mind, because the reviewer managed to match a dustbin to the radio. 8-)

It`s up to Roger to show that his disk experiment disproves skin effect.

Participants here are veterans of previous similar discussions of this
topic. Opinion becomes conviction and conviction becomes intolerance.
Vanity and loyalty produce extremes.

Few opinions change and we have heard all this stuff before.

Here's a rule of thumb equation for you. Determine the resonant frequency of
the 1/4WL vertical, e.g. 3.8 MHz. Multiply that frequency by 2.5 to determine
the 5/8WL frequency. That's close to the maximum frequency for which a vertical
provides good low angle radiation. 3.8 x 2.5 = 9.5 MHz so a 1/4WL vertical on
75m will perform well on 40m and 30m but not well on 20m-10m.

I had a 40m vertical with an SGC-230 autotuner at the base that worked well
on 40m-17m. It is virtually impossible to keep common mode currents off the
balanced line when feeding a monopole against ground.

If your 2m SWR is high enough to require an antenna tuner, it is so
high that you will lose a lot of your transmitted signal unless you
are using very expensive coax or unless you put the tuner at the antenna.

To turn your thinking up side down and save yourself having to bury 4 miles of radials: Consider a top-fed inverted L. Feed the antenna at the top center and run an equal length wire horizontal and vertical. Top feed means no radials. I use 51 feet on a side and tune 160-10 meters. Makes a nice pattern too. See http://www.cebik.com/gup/gup25.html and http://www.cebik.com/ltv.html

Jacques

Feedline losses at HF are fairly low. At VHF, even fairly expensive feedline has considerable loss.

When you put an antenna tuner between point A and point B, it attempts to match the SWR between those points. If you put the tuner between the feedline and the transmitter, power will be effectively transferred into the feedline.

However, the feedline still has a characteristic impedance of 50 ohms, so there is a substantial mismatch where the feedline meets the antenna. This mismatch causes the current on the feedline to be higher than it would if it were matched. This higher current causes the loss on the feedline to be higher, depending on the degree of mismatch, perhaps many times higher.

At 80 meters, I might have a feedline characteristic loss of, perhaps, 0.3 db or so. Even with a fairly astronomical SWR, it might bump that up to 3 or 4 db, measurable, but not really noticeable.

At VHF, however, that same feedline loss might be 2 db to start with (25 meters of RG-8 solid dielectric). Given the same SWR at the antenna, the actual loss might be 20 db, certainly not something that can be ignored. If you are asking this question, you might be using an even smaller feedline. At 2 meters, 25 meters of RG-58A has a characteristic loss of almost 6 db. Hit that with a significant SWR and almost all of your power is being used to heat the coax!

So at VHF, there are a few different strategies that folks have suggested. The most obvious one is to make the antenna resonant in the first place. At 2 meters, a dipole is barely over a meter long. Few people face such space limitations that they can't get a meter of wire in the air. Another approach is to put the tuner at the antenna. This solves the problem of current on the feedline, but it means that you often need some sort of remote control to adjust the tuner, unless you will be operating over a limited frequency range. The third strategy is to get feedline whose characteristic loss is lower. Depending on the length of your run, this can be an expensive alternative. You are typically talking hardline which can easily cost 10 euros per meter or more, and which is a pain to install, or some sort of purged system which could run into many thousands of euros.

This is why so many folks said, why not just make the antenna resonant in the first place.

Now, all that being said, suppose you have a system where the SWR over the range you want to operate is, say, 1:1 at the center, and 2:1 at the edges

of the range. I would suggest just ignore it, presuming you measured the SWR at the antenna. There's another gotcha here that is more of an issue at VHF. If you see 2:1 at the transmitter, and you have a fairly typical feedline, then the SWR at the antenna is much higher. Those same losses are making the SWR at the transmitter appear better.

Hope this helps

..

Source record: 134553

Hi,

I'm trying to build an 8 element Quagi antenna for 434MHz. In Wayne Overbeck's article, he says that he developed the antenna using type TW 12 gauge solid copper wire. He goes on to say that if you can't find type TW wire that some people have used the more readily available THHN wire but that the driven and reflector loops must be made slightly larger to compensate.

My questions are: (1) Does anyone have a source for genuine type TW 12 gauge solid copper wire? I only need 5 feet of it. And if not... (2) How much longer should the loops be made if using THHN? By slightly larger, do they mean 0.1 percent, 1 percent or 10 percent?

Thanks,

Bruce

Hi Tom,

Gary, our original poster would be most representative of them to offer a sieve method: ask them something technical like how high is your antenna mounted? The conventional (antenna designer) response is quite often found in microseconds - if in fact that original poster (the conventional designer) hadn't already offered it as a matter of common sense. [Thus an indirect measurement, in terms of time lag - the conventional vs. eh/cfa/fractal/go response ratio runs on the order of 10ï¿½ï¿½:1 or more (see following).]

Two days after asking this question, I can only imagine the difficulty in responding must be in deciding whether to measure it from the top down, or the bottom up. After tackling the technical intricacies of the eh/cfa/fractal/go, those developers appear to suffer a drain on their capacity to respond to these new technical challenges. Often the impression gained is that they lose interest almost immediately following their bright and cheerful announcements - suggesting problems of a bipolar issue.

Ask them about the circumference of their D-Plate if you want to engage them, but you have to move quickly. Their attention span seems to be eclipsed by the half-life of a Muon.

Another frequent stumper is: did you choke your transmission line?

Or: how much power do you apply to it to radiate one watt? (The answer to that could easily be "at least one watt," but, again, the stump factor has them speechless. You can recognize the alphas of this group who unhesitatingly respond: "I am excited to reveal my design, that I developed for myself, to my great effort, requires half a watt!")
[Note, this last reveals another metric sieve described below.]

Or: Howcum you guys drop in to offer exciting news; only to bail out with the first post? (Almost like slick-willy another one-time poster who last asked about fractals - and on his heels appears a marketing director to offer the good news. ;-)

One sure fire way to engage is to ask: How good? [Keep the question short - remember half-life.] Count the number of words in response and divide by the number of syllables. That measure frequently runs to slightly higher than 1.0. The odd thing about this, is the data pool is sufficient to offer high correlation to this metric, but the data itself contains no information. This is an example of the "fractal paradox" (two phD lecturers presenting one paper).

Another metric is to count the number of times the poster speaks in the first person about technical issues. When the count begins to exceed 10 or 12 "I," "me," "my," and so on in one paragraph (see short example above) - you have to honor the catch and release provision to allow that chum back into circulation. Gary ran to three personal references in a sentence (if one could call it such); but that was "one that got away."

Oh, and as you may have suspected, if it makes as much sense to talk fish as antennas with these folks, you have a boolean metric to serve as another sieve.

Hi Richard,

I would raise that one offering another consideration: destructive
flexing. If the paint can't stretch as much as what is painted,
delamination results.

I can't say I have much to offer in that regard, but when I helped a
buddy replace a radomed collinear 10M antenna from the peak of his
tower, I was shocked by its appearance.

The surface had a fine haze of broken fiberglass strands - none more
than a quarter inch in length. It had the appearance of peach fuzz
covering nearly the entire surface of the radome. The initial glance
at it caught my attention, with my hand exploring the surface before
my mind engaged. Luckily I didn't draw my hand along the surface as
the prickly sensation was immediate.

The prospects of a mitt full of glass wasn't so worrying as finding
that same fuzz busted loose and air borne....

>Daniel Hallas

Hi Daniel,

You describe a very good situation to be in. Close quarters, direct view, and more power than you need.

If you put "rabbit ear" style antennas at both ends (and still turn down that power if you can) you will do very well. This is to suggest that the antenna is not critical, but for the sake of the transmitter should be "tuned" - a consideration I suspect is too technical for your needs.

One problem that could come from too much power (you really need to turn it down) is reflections from nearby walls, local clutter, what-have-you, so large that they cause data degradation. You may build a high speed link, but throughput is going to be in the basement. Technically this called "multi-path" and its solution is found in using high gain antennas that have a directionality characteristic. This is like the roof top TV antennas that had to be pointed at town to see the game. Again, you would need even less power for these to accomplish your link.

Oddly enough, the specs you offer sound like the class of gear I used to teach in the Navy. This is a tactical communications band last I heard... if the current administration hasn't auctioned it off yet.

Given the ambiguity of your credentials or right to operate this equipment: I would caution you, possession of a transmitter is not a license to use it. Its illegal operation can lead to substantial fine and jail time - especially in those frequencies. The height and power you have available makes your transmitter a serious interference

source which in this age could be construed as subversive activity.

The naive are the first casuality of war.

I can see that the lines locally on each surface would reinforce, and that
the lines on opposing sides of center on each surface would oppose
(therefore cancel at a distance).

With skin effect in play, the lines on one surface should not penetrate the
disk to influence the lines on the other surface. Right?

I'd like to build a noise gate circuit for my HF receiver, to be located externally between the radio and antenna, but I'm not sure how to wind the toroids. The circuit I'm going to use (unless someone can suggest a better one for HF use) is at
http://www.lwca.org/library/articles/jtreed/gate/gate1b.htm

This uses two FT50-75 toroids and I understand I need to change these to FT50-43 for hf use (1.8- 30 Mhz). For 50 ohm input/ ouptut, how would I wind the toroids using 43's?

Thanks,
AJ

Hi everybody,

I am a bit perplex about your replies. This is why.

In the ARRL antenna book 17th edition, on page 24-16 (also in ARRL handbook 78th edition at page 19-5)you can see a diagram about loss in coaxial lines. At 150MHz, the matched attenuation of 100 ft of RG8 is just above 3 dB. Keep this figure in mind.

On the other hand, in the book of W2DU "Reflexions - Transmission Lines & Antennas" - 1st edition by ARRL, at page 1-5 you can see another diagram giving the additional loss caused by mismatch for various SWR (also at page 19-6 of ARRL handbook year 2001/ 78th edition). Imagine we have a SWR of 3. The diagram gives an additional loss of 1 dB due to mismatch for an attenuation of 3 dB in matched conditions. This is the consequence of the conjugate impedance theorem or the maximum transmitted power theorem. Total attenuation will thus be 4 dB instead of 3. (In the 80m band the match attenuation would be a bit less than 0.4 dB plus an additional loss of 0.2 dB for unmatched conditions (see also page 1-15 of W2DU book). Those figures could also be obtained from equations.

Is this small 1 dB additional loss at 150 MHz worth to climb at the top of the pole and the price of a remote controlled tuner ?

AJ,

Don't be too disappointed if the thing doea not work. I built something like thi some years ago, got only marginal results on a good day. What I discovered was that:

1. The noise phase during positice AC cycles was not the same as during negative AC cycles.

2. There was sometimes more than one noise pulse during a half cycle of AC.

3. The phase of the noise jiggled back and fourth.

4. The noise "pulse"can be very wide; that is, it showed ringing

Hi Tom,

You are absolutely right on this point. Nevertheless, I didn't feel skilled enough for the selection and I only replied to the original questions:

>I would like to see if any one out thereis useing the e/h antenna and if anyone has build and 75 meter e/h dipole
I would like to see your drawing...I have build e/h for 20 meter and 15 meter there work great on dx last weekend
work 15 dx and 20 states fron maine to SD

Bye.

5325. multiband loop antenna??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-19 19:32:28 UTC
From: denton <denton@oregontrail.net>
Message-ID: <amd8l7$4se$1@news.apaynet.com>
Source record: 134566

Hi all...
I modified my multiband dipole, fed with 450 ohm twin lead, into as much of a loop as the current support structures (40' in the middle and about 27' or so at the ends) would allow and still be about 7 feet or so above the ground at the bottom. My house is the bottom support.
The antenna loads nicely on all bands except 160 and has a bit better noise rejection to the dipole. Radiation pattern seems to be good on the other bands...if can hear them, can work them.

I am thinking of running an 80 meter loop skywire around the property and am wondering if I would notice much improvement over the above.

Thanks for the replys, de Denton, WB7TDG

5326. What type of simple HF antenna to use for DX for this location?

My home is on the east side of a hill about 2 miles from the Pacific Ocean, and the lot has 3 very large cypress trees on the West side. Most of the hams around here have beams pointing West, but I can't do that, because I'm blocked by the trees and the hill. I'm now using a multi-band dipole running East-West, but reception and transmission is not very good. If I run it North-South, it's even worse. Any suggestions? Kevin AC6ME

Then, strip the insulation, and using 5-8 foot (152.40-243.84 cm)
pieces, clamp one end firmly in a vise and chuck the other'n in a
electric hand drill. Twist the wire, whilst pulling it taut, until
you have about two+ twists per inch (per 2.54 cm.) You'll be happier
with it's new found straightness and its stiffness.

Works well with aluminium wire, too. When working with 10 or
8 gauge stuff, use a 3/8" (0.9525 cm) to 1/2" (1.27 cm) drill and
limit the twists to less than 2 per inch (per 2.54 cm.)

I've made 2M vertical yagis out of 8 gauge aluminium wire that have
held up well using this 'trick'. Horizontal --- I don't think it
could cope with birds and/or ice. (Ice is not a problem at this
QTH -- big ravens *are*.)

For the 70 cm (27.559055 inch) band, the 8 or 10 gauge stuff would
probably work out ok for horizontal antennas.

Source record: 134371

Roger, W7WKB wrote:
"With skin effect in play, the lines on one surface should not penetrate the the lines on the other surface."

Two fields, electric and magnetic. The electric is blocked by a conductor shortstopping electric lines and grounding them out. The magnetic field is blocked by counter-emf which is generated and which opposes the flow inducing the counter-emf.

A conducting picket fence only allows magnetic coupling because it inhibits conduction between pickets, except on one end, so no circulating current or counter-emf of consequence is generated. The pickets are effective in grounding the electric field, so it`s blocked and only magnetic coupling is allowed by this electrostatic fence called a Faraday screen. All the pickets are grounded on one end only.

Roger`s disks are small in terms of wavelength and the magnetic field on one side wraps around both sides of the disk. The current flowing away from the wire on one side of a disk is flowing toward the wire on the opposite side of the disk. The lines of magnetic flux are almost concentric as produced by current on the surfaces of the disk, and the lines are perpendicular to the current flows on either side. Since the current flows are reversed on opposite sides of the disk, away from the wire on one side and toward the wire on the other side of the disk, the magnetic fields are reversed and tend to cancel.

It is a mistake to think magnetic lines of force don`t penetrate a conductor. It takes high magnetic permeability to block magnetic lines of force. Recall Terman`s explanation for skin effect. The inner fibers of a conductor are surrounded by more magnetic lines of force (magnetic lines are inside the conductor), produced by current through the conductor, than are the outer fibers. Thus, the innermost part of the conductor has a higher inductance than the outer part. Current takes the easy path which is the outer part of the conductor. Current flows where the impedance is lowest.

A conductor can be penetrated by magnetic lines of force. Counter-emf in a conductor can negate a magnetic field. It`s not the inpenetrability of the metel itself, unless it`s mu-metal or some such, which blocks magnetic lines of force.

Roger has observed that his disks do little if anything to alter an antenna where he positioned the disks. That is evidence that the disks have little if any inductance.

Best regards, Richard Harrison, KB5WZI

That 3 db loss is for a matched condition and no antenna tuner will be needed. If the swr of 3 is measured at the transmitter end and you have a 3 db loss in the transmssion line , look up how much of a mismatch you will have at the antenna. It is almost off the scale. The coax can be open and you will only measue a swr of about 3 with a 3 db loss in the line at 150 mhz. Then check out how much additional loss you get with a swr of 20 or greater that you will actually have at the antenna.

5332. TV antenna ?? from Greenie = Can you stoop this low?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-19 21:57:03 UTC
From: TCS <dollardoc@ezl.com>
Message-ID: <3D8A482F.B4DA0F41@ezl.com>
Source record: 134373

Searched and scanned this group for simple questions re my
TV attic antenna....
Bldg a home on hi hill facing TV transmitters 35 mi away.
Installed big 144" 50+ lead rod antenna in attic (clear view
view to city) and test tv worked great on one 45' lead.
To connect 4 tvs, I installed a 110v splitter/amplifier and
4 coax runs, 25-45' each, but it diminished the signal to
the test TV. The amp/splttr has no power yet in the attic,
so the 4 runs are not boosted in any way. I'm hoping that
powering the amplifier will bring back the great reception
when only 1 lead was run.

Questions:

* It worked great on 1 lead. Can I assume there's enough
drop from the 3 added runs that the test tv was
weakened?
* The amplifier/splitter is in the attic @ 5' from
antenna, but no 110 hooked up yet. Don't know specs on
amp except it cost $39.95 @ Home Depot, and looks like
most single units on internet = 1 input, 4 outputs. Is
this ok?
* Coax was cheap, $40 for 500' box roll. I threaded it
myself by stripping insul @ 5/8" to copper, then
another 1/2" to mesh. No foldbacks, just clipped off
the nylon mesh. Used screw-on coax connectors, made
sure that white inner insulation went through connector
hole and the copper wire extended 1/16 - 1/8" out from
tip. It worked great on the single lead but weakened
when I hooked up the other 3. Do you think cheap coax
or faulty connectors are the problem?

Sorry to take up time with this. Contractor is "closing up"
the house next week. Any changes to the attic antenna or
pre-wired cables need to be done soon. Thanks for this great
site. If you know other links or newsgroups, redirect
please. TOM dollardoc

5333. Re: Follow-up Disk Skin Effect Experiment

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-19 22:33:24 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3D8A50B4.2090303@eznec.com>
Source record: 134374

Neither a time-varying electric nor magnetic field can be produced in isolation, the claims of the CFA and EH folks notwithstanding. Beyond the near field, the ratio of E to H is determined solely by the material, and is known as the intrinsic impedance of the medium. In a perfect conductor, the E field is zero. The H (magnetic) field is, therefore, also zero.

From _Introduction to Electromagnetic Fields and Waves_, by Charles A. Holt:

"To determine the tangential component of the magnetic field intensity H, we shall apply the Maxwell-Ampere law to the rectangle of Fig. 9-7, with medium 2 regarded as a perfect conductor. Time-varying fields are assumed, and the surface current density Js is directed into the paper. The mmf around the path of the rectangle in a clockwise direction is Ht1*{delta}l, because H is zero inside the perfect conductor. . ."

And from _Engineering Electromagnetic Fields and Waves_ by Carl T.A. Johnk:

"Case B. One region is a perfect dielectric; the other is a perfect conductor. Electric currents are limited to finite densities in the physical world. Thus from J = {sigma}E, the assumption of a perfect conductor in region 2. . . implies that E2 in that region must be zero if the current densities are to have, at most, finite values. Moreover, with electromagnetic fields satisfying {del} cross E = -j{omega}B, one can see that if E2 is zero in region 2, then B2 must be zero there also. Thus for time-varying fields, {sigma} -> 0 implies E = B = 0 in a perfect conductor."

In a real, non-perfect conductor, the E field decays exponentially from the surface and, in a good conductor, rapidly approaches a very small value a small distance below the surface. Because the ratio of E to H is constant for the material, the H field decays at the same rate (although the E/H ratio is much lower for a conductor than for a dielectric, so the H field is proportionately greater). The notion that a time-varying magnetic field goes right through a conductor while the electric field is stopped is incorrect, as the above textbooks explain and as a wealth of experience with and measurement of shielding properties confirms.

KJ I have a similar situation only I am blocked to the East and clear to the West. With a modest TA-33 at 30 feet I can work all kinds of DX out in the Pacific. However, East coast is a real stretch with signals sitting at s-7 to s-8 when I know others can hear them at 10 db over s-9. I've thought about this and the only idea I can come up with is to get whatever I use as High as possible. This lets off the beam because of tower requirements. However, I should be able to put up a light weight ground plane as high as 50 feet. I am hoping this will enable me to clear the hill on all but the lowest of angles. At times I am able to work the East with less difficulty I theorize this is because it is multiple hop propagation arriving at a higher angle. The lack of beam directivity during these times seems to bear that out. Something like the old mosely or high gain trap verticals for 20-15-10. They were only about 12 feet or so and the maximum height might be more reasonable. (50 + 12 = 62 which still may be too high). Since my problem is simialr I'd like to hear what your solution is.

Tony

Thank you Ralph for your reply. About the exemple, I haven't see yet in those books if the SWR is supposed to be mesured at the antenna or at the transmitter end. I think I will put this example in a Smith' diagram just for seing what will happen. Anyway an SWR of 20 at the antenna is not realistic because it would require first some adjustment at the aerial. So my assumption of a SWR of 3 or even 5 could be reasonably good and in this case the books are right.

They are far from defunct. Mostly advertise in mags such as QST (small
ads). I have an 85' W9INN 80/40 meter dipole and it works great.
Totally flat across 40 meters, never more than 1.2:1 SWR, and fairly
broad on 75 meters.

On the air reports give me 1-2 s units over my old G5RV. The W9INN's
are great antennas.

With the preamp not powered up you are inserting loss. Most cheap preamps will not pass much of anything until they are turned on. Run some juice to it. You will probably do fine then. As for being equal to a single run. No way of knowing without the specs on the preamp. I.E. Gain and insertion loss. Just fire er up and see.

"TCS" <dollardoc@ezl.com> wrote in message news:3D8A482F.B4DA0F41@ezl.com...
Searched and scanned this group for simple questions re my TV attic antenna....
Bldg a home on hi hill facing TV transmitters 35 mi away. Installed big 144" 50+ lead rod antenna in attic (clear view view to city) and test tv worked great on one 45' lead.
To connect 4 tvs, I installed a 110v splitter/amplifier and 4 coax runs, 25-45' each, but it diminished the signal to the test TV. The amp/splttr has no power yet in the attic, so the 4 runs are not boosted in any way. I'm hoping that powering the amplifier will bring back the great reception when only 1 lead was run.
Questions:

a.. It worked great on 1 lead. Can I assume there's enough drop from the 3 added runs that the test tv was weakened?
b.. The amplifier/splitter is in the attic @ 5' from antenna, but no 110 hooked up yet. Don't know specs on amp except it cost $39.95 @ Home Depot, and looks like most single units on internet = 1 input, 4 outputs. Is this ok?
c.. Coax was cheap, $40 for 500' box roll. I threaded it myself by stripping insul @ 5/8" to copper, then another 1/2" to mesh. No foldbacks, just clipped off the nylon mesh. Used screw-on coax connectors, made sure that white inner insulation went through connector hole and the copper wire extended 1/16 - 1/8" out from tip. It worked great on the single lead but weakened when I hooked up the other 3. Do you think cheap coax or faulty connectors are the problem?
Sorry to take up time with this. Contractor is "closing up" the house next week. Any changes to the attic antenna or pre-wired cables need to be done soon. Thanks for this great site. If you know other links or newsgroups, redirect please. TOM dollardoc

Considering that you are operating in a military band used extensively
for satellite and airborne communications I would suggest a "very"
narrow beam antenna. Especially with the current state of military
alertness I would not want to be even suspected of interfering with
military communications systems.

With the original style "NM" (Romex brand, etc.) cable, you get 60C
rated wires (TW). But the newer "NMB" cable has 90C rated (THHN or
THHW) conductors, iirc. Low temp wires have fallen out of favor,
because ceiling light fixtures often run too hot for them. Thus you
have trouble finding TW style wire in retail stores these days.

Since neither type is sunlight resistant, I suggest you re-calculate
the lengths for bare wire, and use the uninsulated ground wire from
the Romex cable. The antenna won't de-tune as the sun cracks the
plastic and the wires turn bare. NEC, etc. should work fine with the
bare wires, so you can let the computer do the calculations.

True, but this is totally irrelevant to a disk impaled on a wire. Why Roy attached my posting is a mystery.

Terman, in the 1955 edition of "Electronic and Radio Engineering" on page 38 at the bottom of the page writes:
"It is possible to shield electrostatic flux without simultaneously affecting the magnetic field by surrounding the space to be shielded with a conducting cage that is made in such a way as to provide no low-resistance path for the flow of eddy currents while at the same time offering a metallic terminal upon which electrostatic flux lines can terminate."

Terman was not commenting on the CFA or EH antennas and neither was I. We both were commenting on circuit theory, not radiation. I have often been wrong, but I`ve never found Terman wrong.

There's a chart in the ARRL Antenna Book that indicates for an SWR of 3:1
at the transmitter and 3dB matched line loss, the SWR at the antenna is
about 75:1. Fig 25, page 16-15, 17th edition, 1993.

Roy, W7EL wrote:
"The notion that a time-varying magnetic field goes right through a conductor while the electric field is stopped is incorrect---."

A Faraday screen does exactly that!

See my immediately previous posting.

On page 21 of the 1955 edition, Terman says:
"A simple example of skin effect, and one that makes its nature clear, is furnished by an isolated round wire. When a current is flowing through such a conductor, the magnetic flux that results is in the form of concentric circles, as shown in Fig. 2-9. (Yes, a circle of the magnetic flux is shown within the wire.) It is to be noted that some of this flux exists within the conductor and therefore links with, i.e., encircles current near the center of the conductor while not linking with current flowing near the surface. The result is that the inductance of the central part of the conductor is greater than the inductance of the part of the conductor near the surface; this is because of the greater number of flux linkages existing in the central region. At radio frequencies, the reactance of this extra inductance is sufficiently great to affect seriously the flow of current, most of which flows along the surface of the conductor where the impedance is low, rather than near the center where the impedance is high."

There is much more that Terman says, and I don`t think I contradicted any of what Terman says. He is virtually infallible, so I am secure in what I posted.

5351. Carolina Windom, G5RV or convential dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-20 04:57:25 UTC
From: rhmcus@yahoo.com
Message-ID: <3d8ba8b9.323183913@news.us.dell.com>
Source record: 134392

All

I currently use a full sized G5RV with good results. I use it primarily for 80 meters although I have ventured down to 20 with good luck. I also have a Gap Titan DX which is very good for DX however at night the G5RV is clearly superior.

Several guys n 80 are trying to persuade me to take down the G5RV in favor of a conventional 80 meter dipole or perhaps the carolina windom. I'm using the G5RV in an inverted V formation and due to space restrictions would have to use any other wire in the same manner.

What is every ones thoughts on this? Which is a better multi band antenna? I know that sometimes a multipurpose antenna is a compromise.

Thanks

Rich KG5IF

I was responding to your assertion that:

"It is a mistake to think magnetic lines of force don`t penetrate a conductor. It takes high magnetic permeability to block magnetic lines of force."

I have the 1947 edition of Terman, and the quote you give appears on page 37. A half page or so earlier, however, he states:

"At radio frequencies and at the higher audio frequencies, more satisfactory shielding can be obtained by the use of shields having high electrical conductivity. Magnetic flux in attempting to pass through such a shield induces voltages that set up eddy currents that in large measure prevent the magnetic flux from penetrating through the shield (see Fig. 2-16). To be effective, a conducting shield should have a thickness at least several times the skin depth . . . Under these conditions, the ratio of magnetic field intensities existing on the two sides of the shield is

Ratio of magnetic fields = 2 * e^(-a/d) ~ 6 - 8.7(a/d) dB."

[End of Terman quote]

Here, d is the skin depth and a is the shield thickness. So, for example, the attenuation of the magnetic field at 10 MHz through a piece of copper, say, 30 mils (36.5 skin depths) thick, is about 312 dB. Now, the ratio of light from an ordinary two cell flashlight to the total light output of the Sun is only about 280 dB, so with 30 mils of copper having a relative permeability of one, we've exceeded this amount of attenuation by about 2,000 times. This hardly fits with the concept of "magnetic lines of force penetrating a conductor". While some theoretician might argue that *some* field gets through, any engineer I've worked with would consider the magnetic field on the other side of the copper to be zero, regardless of how strong it was on the source side. (Actually, it would be virtually impossible in practice to prevent a much, much larger fraction of the field from getting around the shield in some way.) In a perfect conductor, the skin depth d is zero, so the attenuation of the magnetic field is infinite. And this is regardless of the permeability.

So the magnetic field does not simply go unimpeded through a conductor as you implied in your posting. I'm sure you'll agree with Terman on this.

As for separating the electric and magnetic fields, the Faraday cage that Terman describes is different from a solid conductor. It would require wires with no continuous paths (i.e. a gap in anything resembling a turn), among other qualifications. The electric field near

the cage will be much lower than the magnetic field, indeed, but far from the cage the ratio will be right back to what it is for any electromagnetic wave in that medium. For air, that ratio is about 377 ohms. The example Terman gives is typical of a Faraday shield application -- a low frequency transformer, where the near fields are being manipulated.

You will need elevated radials from the feedpoint of the antenna, if you want it to work tower mounted. Unlike having radials on the ground, which are detuned by the ground, elevated radials must be resonant. Usually 1/4 wave. And you would need at least one radial for each band to be used. More would be better. Is it worth it over a ground mount? I think it is, as long as you use enough radials. The ground losses are lower the higher up you get. Four radials at 1/2 wave up are about as good as 120 on the ground.
Even four radials at 1/4 wave up will do very well. Thats about like 60 on the ground.
The performance on the higher HF bands will almost always be a good bit better on the elevated antenna. If you do any ground wave locally, say on 10m, it will be much better.
I ran a 1/4 wave "32 ft tall" radiator on 40m. First on the ground with 24 radials, and then later at 36 ft up , with four radials. The elevated antenna was much better than the ground mount on 40m. As far as the radiator and coil or caps needed for loading, etc, no difference with that no matter where you install it. The only thing that changes is the ground loss number. And that is no real relation to the radiator. 21 ft is a good number for an all band vertical. Just about right as a 5/8 on 10m, and still tall enough to be decent even down to 40m. Will work on 80m too if you can live with a cut compared to a 1/4 wave. The more top or capacitive loading the better. IE: hats , spokes, etc. MK

One additional thing to remember is that wire dipoles (which are frequently used on HF with a tuner) have a quite simple radiation pattern and hence, the gain is quite low. Operating the antenna slightly off resonance (with a tuner) does not radically alter the radiation pattern or gain.

However, yagis with a large number of parasitic elements (as usually used on VHF/UHF) heavily depends on the various resonance frequencies of the various parasitic elements. Even if you operate the radiating element (with a tuner) slightly off the design frequency, all the parasitic elements are still operating at the original design frequency, thus the radiation pattern will quickly deteriorate when operating away from the design frequency. Since antenna gain is simply the ability to concentrate power to the desired direction (and multiplied by the antenna efficiency), the gain will also drop outside the design frequency. In the worst case, trying to use an antenna tuner (even at the antenna) with its internal losses will reduce the antenna efficiency and also reduce the true gain of the antenna even further.

Thus, this is an additional reason why antenna tuners are not used on VHF/UHF.

Hi Jose,

You will notice from the other responses, that many consider your request odd. There is little that readily translates from the discrete tuning elements of HF to VHF/UHF; and you would probably find the standard tuner of these bands more appropriate: the single or double stub tuner.

Laboratory models are coaxial, with variable length out to ï¿½ meter. You don't need to have much more variability than that, but you do need some freedom to move it (with a T connection) in relation to the load. This is the major difficulty with a single stub tuner being applied to a wide variety of loads. When you expect to encounter this variety, then double stub tuners (or simply two single stub tuners, separated by an arbitrary distance) are preferred.

Roy, W7EL wrote:
"I was responding to your assertion that:
It is a mistake to think magnetic lines of force don`t penetrate a conductor. It takes high magnetic permeability to block magnetic lines of force."

Yes, and I explained more than once that the mechanism of thwarting a magnetic field`s penetration of a conductor may be different from thwarting an electric field.

The electric field is short circuited. The magnetic field iis opposed by an "eddy current" according to Terman. Eddy current is a good name because it implies circular motion, and that is exactly the current motion a Faraday screen prevents. This eddy current is often stopped by a series of vertical or horizontal slots cut nearly all the height or width in the Faraday shield. Current motion is limited to up and down or from side to side but it is not allowed to freely "circulate".

The slots in a Faraday shield kill its generation of a counterforce which would make it an effective shield against the magnetic field. So, the magnetic field is not inhibited significantly by a Faraday shield. The electric field, however, is very effectively shielded by the design of the shield. It would be possible to make the shield too small or too gappy to be an effective electric field shield but that would defeat its purpose.

I am not referring to the electrostatic shield in a power transformer, but their action is about the same. I am referring to the Faraday shields used in all the radio stations I`ve worked in. These are used in broadcast stations to eliminate capacitive coupling to the antenna because capacitive coupling favors harmonics. The Faraday screen kills capacitive coupling by blocking the electric field. It gets shorted to ground. A good short doesn`t lose any energy.

A coupling transformer is often used to feed an antenna. The Faraday screen is placed between the primary and secondary coils. Though the electric field doesn`t get transferred to the secondary, magnetic coupling simultaneously produces a new electric field in the secondary as current flows in the coil.

As for Terman`s elaboration on high-permeability, he was writing an excellent text book and I was only making a reference in passing on the way to a newsgroup posting.

Best regards, Richard Harrison, KB5WZI

Hi dear CAM,

We are not speaking about the same things. I never told about a SWR of 3 at the transmitter end of the line in the conditions of attenuation you described. I only told that if Jose Luis (as told in his original message) needs an antenna tuner, why putting it at the antenna end. It is common sense, if he has a very bad SWR at the aerial, he must first cure the problem at his antenna. In this case, my assumption of starting with a SWR of about 3 AT THE ANTENNA is quite reasonable. The rest is obvious and corresponds to my previous posts.

BTW I never found the chart you mentionned at the page / chapter / edition / book, indicated in your last message. Can you check and repost the reference. Thank you.

Hallo everybody,
I'm looking for someone using B&W AP-10A antenna,
short and telescopic HF mobile antenna.
I'd like to know more about the A verison...
I'm using now the 5 coils version... it's quite boring.

bye for now
pse personal answer

I have for sale 1 full size "HY-Gain" beam 10 meters. fully assembled for your inspection. 13' Boom and longest element is 22' $75.00 I also have a steel tower totaling 25'. this is in 3 sections 1 10 foot st8 and 1 5foot st8 and 1 10 foot top section. I don't not have a rotator. $50.00. pickup only from Nashua,NewHampshire. I am selling these because they are to big for my new QTH. This beam has spent a large portion of its life in storage. 73's Jeff AA1GR

That's what railroad locomotives use. It's called dynamic breaking -
turn the traction motors into generators and dissipate the generated
power in high-wattage resistors cooled with fans as you go down hill.

Richard Clark wrote:
"The surface had a fine haze of broken fiberglass strands-"

Remings me of hard sells for fiberglass dishes to replace aluminum. The reflecting surface was applied as seen on fake chrome items made of plastic. All the VHF antennas made of plastic we had tried proved short lived as compared with our stainless steel models. So, I never bought a fiberglass dish because there was no problem with the aluminum models.

Seen a number of ripped high-performance dish covers made of fabric.

I suppose wind-driven rain could wash away paint as particulate matter is reported to do. High pressure water is used for paint removal in some cases.

The only tower painting problem that I recall was using a new epoxy paint touted as permanent. It was only permanently wet. The epoxy never hardened.

Best regards, Richard Harrison, KB5WZI

A ham I know tested the loss at 2 meters through 100 feet of cheap RG8X
coax into a dummy load. Driving the input with 45 watts he found the
wattmeter at the load end measured 5 watts.
That was into a MATCHED load, 1:1 with nothing reflected.

Don't make too many assumptions about hills, trees or mountains while dealing with HF. They are likely to be wrong since there are a lot of variables involved. Chances are they won't seriously affect your transmitted signal and almost certainly won't seriously affect your reception.

You didn't further describe your "multiband dipole" but if it is a commercial trap dipole be aware that many of those won't work well out of the box. Friend of mind bought one and never did get it to work and finally sent it back, not wanting to have to reengineer it. I use paralleled dipoles hung as high in the center (feedpoint) as feasible and tied off whatever is convenient, matched at the line input with the rig's internal autotuner. Works out well.
But you're never going to compete with your pals' beams unless you decide the hill and trees aren't so much in the way after all. Unless the hill or the trees are extremely close, your beam will probably never know they're there. My HF yagi snuggles among a bunch of giant oaks at ~50 feet or so and as far as I can tell they don't affect its operation.

Wellll... I would consider getting decent performance from a
trapped/loading-coil/cut-down dipole on at least two bands to
be a bit of engineering, particularly if one doesn't use
any capacitors. More going on there than that which first
meets the eye.

Unfortunately, W9INN's expertise apparently doesn't extend
to creating a definitive website for the cyber-shoppers
among us to practice our specsmanship upon.

Don't worry, you're not alone! I checked on the same 17th edition and only
found a 'drilling template for...'.
But I found my 17th edition is a second print of '94.
Fantastic! I suppose the first print of '94 is something different too!

hi,
I am writing a log-periodic antenna design software pakage. but I do not have enough equations and I haven't decided which programming language to use yet.
I would like to have the equations of finding the surrent and voltage distribution of the dipoles when a signal of frequency f is recieved or sent. I also need the equations of finding the radiation pattern.
please help me if you have these equations. any suggestions of what to include in the pakage and the programming language to use are welcome.
thanks a lot.

Hi Rich,

Sounds like your buddies are lookin' for change - at least in the
copper. Are they bored?

You are happy with the present G5RV. You are also well aware of the
limitations of both the designs and available space. Your intuition
seems to be in working order.

Solution: tell the guys you followed their advice and they will
respond appropriately with better reports. You may also notice that
those in the group who thought you should keep the G5RV might gripe
about the loss of gain - who knows? You can swap sides every month or
so by saying you changed again. You may become the group antenna
guru.

I doubt your DX contacts will notice either way. ;-)

Rich,
A multi-band antenna is always a compromise, and
your friends on 80 meters are right, a conventional
dipole (especially if fed with ladder line through a
tuner) will do as well, if not better than the G5RV.
'Doc

The original G5RV was not intended to be a 'multi band' antenna. It was designed to use on 20 meters as a 3/4 wavelength and provide a bit of gain and directivity.

It also didn't have a balun. It was originally fed with 300 ohm line.

Its performance on any other band, other than 20 is, IMHO, lacking.

I agree that a 80 meter half wave fed with ladderline would do better. I know for a fact that a half wave fed with coax as compaired to a G5RV does work better. I have done it and know.

Source record: 134321

Arnold B. Bailey in "TV And Other Receiving Antennas" discusses ways to make antennas perform over a 4 to 1 frequency range. Here are a few points from "Dual Frequency Zero-db Antennas" on page 420 (not verbatim at all).

A 1/2-wave dipole at 4x first resonance has a null broadside (Fig 16 page 2-12 ARRL Antenna Book). One way to fill in the null is to tilt the dipole sides toward the signal. Another way is to add whiskers at certain points on the sides of the dipole. A loop or stub around the feedpoint is yet another filler (Art Unwin`s antenna?).

A 1/2-wave dipole has only one current loop, with its maximum at the feedpoint. At 4x the frequency there are 4 current loops, 2 positive and 2 negative, and their sum causes the broadside null.

The open circuits at the dipole ends cause the current maxima and minima along the dipole, similar to those caused by standing waves on a transmission line.

Discontinuities can be added to a dipole to modify its standing wave pattern as a way to fill in the broadside null. Whiskers, loops, etc., were mentioned, but the point of this posting is that Roger`s impaled disks are shown as discontinuities to broaden the frequency response of a dipole in Fig. 8-27 (C) on page 423. In this implementation, their positions are made adjustable.

Best regards, Richard Harrison, KB5WZI

Am I understanding correctly? The magnetic field would pass easily through metal except that an induced current is generated below the metal surface that cancels the field and prevents it from passing completely through at full strength.

A Faraday Shield works because it is designed to prevent the induced current from flowing to the magnitude needed to cancel the applied field. As a result, a large component of the applied magnetic field can pass through the metal composing the Faraday Shield.

Is that right?

Glad you brought this up because I had another example of the general
problem right under my nose which didn't click with me.

I was involved with moving a 224Mhz repeater. The antenna is a big,
maybe 20 foot long commercial fiberglass stick which had been up for
many years at some low elevation like 40 feet at the base. It was in
really bad shape. The damage was exactly as you (QHC) describe, a sort
of "peach fuzz" which could do a real number on your hands.

Again the damage was progressively worse from the bottom up the stick
which coincides with my experience with the Rohn 45 tower. I can't say

I particularly noticed any damange which could have been attributed to flexing but I wasn't looking for it. Obviously makes sense that it could happen if the coating is too hard/inflexible.

I sanded the stick and almost choked myself in the cloud of dust that billowed off the thing. I coated it with clear marine epoxy resin and it went back up. We'll see how long it lasts this time.

The folks who engrave tombstones for instance do it by cutting a sheet rubber stencil which is laid over the face of the stone. Then they sandblast the stone. The sand etches the exposed stone but the sand simply bounces off the rubber. Maybe the solution is to apply a rubber coating on towers and sticks.

. . . but then why were my 4el 20m and 3el 15/10 aluminum yagis just about as good as new after 30 years up and the tower had gotten pounded? . . .

OK, let's work backwards. If the SWR at the antenna is 3:1 and the loss in
the coax is 3dB, the SWR at the transmitter is less than 2:1 and there is
no need for an antenna tuner.

If the losses due to SWR in the coax feedline at vhf/uhf are not enough to
worry about, then the impedance seen by the transmitter is probably not far
enough away from 50 ohms to require an antenna tuner. This is one thing that
makes vhf/uhf somewhat different from HF.

Wow, that was cheap RG8x. The wireman says the loss in RG8x on 2m
should be about 4.5dB. Your buddy's loss was about 9.5dB.

A conventional 80m dipole fed with ladder-line would be a slight
improvement. But you probably won't be able to tell the difference.
Take a look at my web page to see why the G5RV is such a good
antenna on 80m and 40m. The "matching section" actually does some
worthwhile matching on those two bands. And, of course, it works
well on 20m, the band for which it was designed.

Yes, that's right. Gaps in the Faraday cage prevent any part of it from looking like a shorted turn, which would produce the counter-magnetic field due to current flowing in it. But do keep in mind that only the local field is affected by the Faraday cage. Beyond the near field, the E/H ratio is back to the value dictated by the medium.

Hello Denton,

A horizontal loop, fed as you are doing with the dipole, will be very quiet
reducing background noise below what you would hear on the dipole.

The loop will require a tuner but I know someone here in Charlotte, NC, with
305 countries confirmed on an 80m horizontal loop.

Good Luck,

Bill, W4WNT

The SWR is usually the ratio of the transmission line and antenna. Unless using part of the transmission line to match the antenna, then the swr should be measured at the antenna. I ahve seen where sometimes a 1/4 wavelenght 70 ohm coax will be used right at the antenna to match the antenna to a 50 ohm line. Also a 50 ohm 1/4 wavelength will be used to match to a 70 ohm trannsmission line. Then the swr will be measured at the end of the 1/4 wavelength matching section that is actually part of the antenna system and not the transmission line. I hope that comes out the way I ment it to.

Most people measuer the swr at the transmitter because it is easy to get to and also it should be checked there to be sure the transmitter is loading into the usually 50 ohm load it is designed for. If the coax loss is low as at 40 meters and below it does not make much differance as the swr at either end will be close to the same provided the lenght is not near a 1/4 wavelenght or other multiple that turns the line into a 'matching segment'. As the losses go up in the coax the swr measured at the transmitter will seem to be lower. You can take about 300 feet (probably less but I did it at this length) of rg-58 and leave one end open at two meters and see almost a perfect 1:1 swr when it should be infiniate.

makes vhf/uhf somewhat different from HF.

I do agree 100%. Even an OM replied me privately a few days ago and we arrived at the conclusion that an antenna tuner is not necessary. And he added:

> A tuner for 2M would, I think, have to face some rather nasty design tradeoffs. You'd probably need to use physically-small components, to keep the tuner's parasitics under control... but such small components would be very limited in the amount of loss energy they could dissipate. If you try pushing 50 watts through small inductors and trimmer caps, in a tuner with 5-10% losses (not unusual for a tuner) you'll probably fry the inductors.

Rethinking, it may have been a bit more than 100 feet. But it was that cheapie silver jacketed stuff that was the rage for awhile. I checked some of it once for braid coverage and you could see lots of center insulation through it. Sure wasn't usable on 2 meters except for very short runs.

Not enough to make it worthwhile to strip the insulation off before you install them. In fact, radials at or in the ground need not be cut to a resonant length. The ground drastically detunes them anyway, and if you want them resonant you'll have to prune them after they're installed. Might be a pretty good chore for those you just buried. :-)

And the boss didn't want to believe me when I told him there was a
defective DB24 antenna on the other end of that 265 foot run of one and
a half inch hard line up on the tower with an SWR of less than 2:1! The
transmitter couldn't be heard out of town where it normally worked over
a hundred miles at 155mHz.
(Installation of a new DB24 took care of the problem. Old one had lost a
couple of weather seals and was waterlogged)

Dick

Our tree in the front yard was hit yesterday. Pretty hefty strike too. I don't know if it branched off to my mast any or not. It mainly seemed to hit the tree only. My brother had just pulled up and parked out in the street. He was just fixing to make a mad dash in the rain for the house, when the lightning hit the tree. He was quite lucky as he would have been partially under the tree when running for the house. It's a big, tall oak tree. Taller than my mast. I was standing near the front door, and I thought it was maybe a couple houses down. I didn't realize it was so close. I asked him how he knew the lightning hit the tree, and he said he could see it running from the base of the tree along the ground and out to the cement of the street in front of the house. I carefully looked at the tree, and I could see lots of real thin "etched" lines running down from the top of the tree. They want all the way down to the ground, and branched off to ground from the roots.
Looks like someone took an awl and dug a thin cut where you see this. You can see bare wood in the middle of these cuts. It's like the lightning took 20 paths down the tree in small split up branches of energy to ground. I was grounded out as usual, and had no damage.
This makes the third strike in our yard in about 4 years. MK

I use mine with a 60 foot wire hung wherever I can find. When camping I use a 10 ft collapsable tent pole for the far end and hang the near end from the luggage rack on the RV with an insulator. I set the EDX2 on a block on the ground under the RV. For a counterpoise I use a 40 ft piece of ordinary small gauge copper "magnet" wire laid on the ground, usually arranged so it's all underneath the RV. Works very well, even on 75 meter SSA.
I've never tried it on any other antenna.

Obviously it's the age factor, the G5RV being "old" accounts for at least
8db. Then too, everyone knows that G (British) antennas are weaker by at
least 8db compared to W antennas.

Yes, indubitably!! In a very good continuous conductor, the counteracting induced field is almost equal and opposite the field imposed on the conductor.

According to Bartlett's _Familiar Quotations_, he said "This is the sort of English up with which I will not put."

Many years ago in "Charlie Rice's Punchbowl" in the Sunday paper magazine, Rice ran a contest to see how many prepositions could be put at the end of a sentence. The winner, with six, took a little explanation:

Father wanted to read little Johnny a story from a book, but Johnny wasn't interested. Angry, Father sent him up to bed without dinner. After dinner, Father decided to try again, so he went up to Johnny's room and offered again. Little Johnny said,

"Why did you bring the book that before dinner I didn't want to be read to out of up for after?"

Wayne,

If you want to work FM, you need a vertical, or a vertically mounted dipole.
For SSB, you need to be horizontally polarized.

As for commercial vs homebrew, whichever one you can get higher up is
better.

G'day,
are there any 'small' (indoor/attic) VLF/LF antennas that are worth building?
10kHz-100kHz would be the most interesting band, I cant roll out several km's
of wire and coupling to for instance the phonelines aren't an option since we use
underground wires here.
Have you tried a design you can recommend?

//Greg

You can wind a ferrite rod antenna but a 10:1 frequency coverage range
will involve some variable tuning components and/or compromises.

Source record: 134361

Bonjour,
Je recherche exp&#65533;riences d'OM qui &#65533;mettent avec une antenne circulaire magn&#65533;tique de marque BABY LOOP fabriqu&#65533;e par une entreprise italienne. Apparemment cette antenne par rapport &#65533; celles d&#65533;crites dans les articles de "construction" et celles de MFJ (1786, 1788...) aurait une directivit&#65533; non seulement avant c&#65533;t&#65533; de l'ordre de 25 dB mais &#65533;galement une directivit&#65533; avant par rapport &#65533; l'arri&#65533;re de 7 dB. Je souhaiterai avoir confirmation de cela car cette directivit&#65533; avant arri&#65533;re permet en th&#65533;orie une utilisation &#65533; partir de la fen&#65533;tre sans pour autant "irradier" l'habitation.
De plus je souhaiterais avoir connaissance des exp&#65533;riences des utilisateurs de cette antenne, &#65533; savoir :
&#65533;les conditions d'installations,
&#65533;dans le cas d'une utilisation sur balcon la g&#65533;ne TVI existe elle pour les voisin du dessous? Quelles sont les configurations &#65533; &#65533;viter?
&#65533;le r&#65533;glage de l'antenne &#65533; l'aide du CV command&#65533; par moteur est elle ais&#65533;e avec le bo&#65533;tier de commande de base ou vaut il mieux d'embl&#65533;e investir dans le bo&#65533;tier de commande avec tuner automatique? Peut on avec le bo&#65533;tier de commande de base , &#65533;tablir selon la fr&#65533;quence utilis&#65533;e une courbe position CV = F(fr&#65533;quence). Le tuner automatique est il r&#65533;ellement une vrai boite de couplage?
&#65533;ce type d'antenne permet il r&#65533;ellement de pratiquer une activit&#65533; de radioamateur? Quelles sont les bandes de fr&#65533;quences les plus appropri&#65533;es?

```
A l'avance merci de toutes ces informations

73 de F5TPK
```

All

Really thanks for the tips.. I have used the G5RV for a good while.. Just haven't got around to changing the antenna type. The beauty of wire antennas is there cheap and usually easy to change out.. I use a MFJ differential T tuner in the shack which works great..

Also have a Gap Titan Dx vertical which I like very well. I can switch between the two depending on signal strength.. The wire all ways beats the vertical on 80meters at night no contest. But depending on the station being worked the vertical may be better. Oh well going off on a tangent here..

Anyway thanks for all that posted and the emails.. I am also looking for some good info on baluns and when they are really needed.

5423. Review : ALA 330 active magnetic loop antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-21 10:11:05 UTC
From: Thierry Lombry <lombryt@hotmail.com>
Message-ID: <3d8c45b9_1@news.vo.lu>
Source record: 134364

Review of the ALA 330 active magnetic loop antenna

Foreword:
This review is first dedicated to SWL and novices hams that have either never seen a loop antenna from their live, nor connected the different parts of an antenna together nor used a multimeter or a similar device. Hi !

The context.
One day or another we all experiment radio interferences due to man made noises. Chhhhhrr . do you remember that sound ? Sometimes severe these undesired signals can easily cover your strongest DXCC and ruin your QSO or cover all your hope to get the QSL of your most wanted DXCC... This is not a problem if the source of QRM is intermittent or occasional. But that becomes a really problem if the QRM is permanent. If your FCC or local radio service cannot help you in solving the problem you have no other choice that moving in a quiet place or finding a way to reduce this QRM.

Then there is the problem of working on the lower bands with an antenna well cut ≈ l/4, what means 40m long on 1.8 MHz ; not everybody can install such a passive antenna in the garden.

At last there is the problem of matching the antenna with the receiver input, in most case that means a 50 ohm impedance to get the maximum signal transfer. So usually in some bands our installation is far to match the desire figures and to transfer all power to the receiver and vice versa. However the main problem stays the QRM.

Currently in the appartment in which I live I experiment much QRM generated by what I suspect to be a poweful source of electrical noise, an air-conditioner (investigation are under way with the help of the local P&T radio service).
I can made this comparison because in another home I use a 40 m long wire tied between 3 and 5m high (see http://www.astrosurf.com/lombry/qsl-longwire.htm) that captures nearly no QRM at all on any HF band. Of course the location explains that : the second one is far from urban environments, on top of hills and allows me to capture nearly all DXCC without consulting the cluster. But in my first QTH, also located in the country but not as quiet as the second, due to a lack of space I had to use a 15m sloper tied outside to the end of the garden and attached to 20m of wire that run indoor across the appartment at ceiling level. This is far to be a performing antenna system. So both installations are not exactly identical but in the last QTH I capture too much QRM : the S-meter exceeds sometimes S-9, with an average level of S-7 ! In others words the noise is permanent. Even my computer (the keyboard control LED, the screen, the reboot/shutdown phases), the scanner, some power supplies or rechargers are also strong QRM emitters.

All HF bands are concerned but mainly the one between 20-10 m, the bands I use the most for DXing in summer. So I could not continue and complete my DX awards this way.

As SWL my first idea was to buy a MFJ noise canceler (see http://www.astrosurf.com/lombry/qsl-mfj1026.htm) but I was not convinced by the result even if it was able to suppress many directional noises. More, the device has to be tuned manually each time I changed of band and even inside a same band due to its short bandpass, and I had to acquire some experience with its three controls to use it quickly and efficiently. So the system was maybe useful but hard to control in some circumstances. So I needed something easier to use.

I searched for another solution that could perform faster and much better in reducing this QRM. So searching on Internet I have found Wellbrook products and its active magnetic loops, that, according the manufacturer were especially designed to remove all QRM generated by electrical sources. Was that my miracle solution ? At first sight I had a mitigated feeling about performances of such small antennas. But after have read many articles about the subject and being not an expert either in antenna nor in electronic, I accepted the challenge and for my SWL activities I bought on the suggestion of his salesman, the ALA-330, a receiving magnetic loop antenna.

What is a magnetic loop antenna ?
In a few words the ALA 330 is a compact HF antenna constituted of an aluminium sheated loop of 1.1m of diameter. It is especially designed to reduce sensitivity at LF and MW to prevent the receiver overload from multiples high power AM broadcast in city areas. Complementary its design help in reducing QRM.
The secret of this kind of antenna is to capture only the magnetic component of the electromagnetic field.
An ordinary antenna, a passive element like a long wire or even a beam, works by capturing the electric field of waves and transmit it to the receiver. However a magnetic loop does not work with this component.
When we know that most devices are electrically powered and can generate severe QRM in all HF bands, the active magnetic loop looks like a miracle solution as it is nearly insensible to electrical sources. It is able to reject most locally radiated noise, like mains wiring, air-conditioner, power supply, fluorescent lamps, dimmer, so much sources of man made noises in HF bands and higher frequencies.

Then about intermodulation, the second and third order intercept points are typically +70 dBm (IP2) and +40 dBm (IP3) respectively. So the level of intermodulation products are well below the QRN and QRM level.
At last the magnetic loop displays a very wide frequency response requiring no antenna tuning. The ALA 330 works in the frequency ranging from 3-30 Mhz and matches directly to the receiver without having to adjust the impedance. This is due to the fact that the current induced into the loop is proportional to the field strength rather than to the frequency. According the manufacturer, the useable reception range practically extends from 150 kHz to over 100 MHz.

More interesting, compared to a whip antenna, the loop improves the S/N up to 20 dB and is able to ensure a very low level of intermodulation in strong signals environments. Due to the interference rejection in vertical position this receiving loop displays a classical dipole Figure-of-Eight directivity pattern that are enhanced by deep nulls.
At last a loop antenna is a compact antenna that requires only 1meter square in the living room or outdoor, practicaly nothing compared to the required space for any other model of antenna (long wire, a dipole or a beam).
So all these advantages made of this kind of antenna the ideal model for people with limited space, interesting in LW listening or experimenting much QRM.

Installation and first mistakes
The product was originally packaged and I suspect the postman to wonder what could hide this huge &#65533; hula hop &#65533;. Imagine how to transport a 1m-loop by mail : all the loop was envelopped in a thick and dense tube of foam, maintained internally with 2 bamboo sticks ! It arrived some weeks later at home in Luxembourg in excellent state without additionnal charges. Ouf !

Being not really an handyman - I do my best sir ! - , and seeing no &#65533; assembly manual &#65533; excepting a small graphic drawed on a technical sheet (the same as the one published on Wellbrook website), I had a few seconds of stress. How could I assembly all that stuff ? The kit contained 1 metallic adapter and three screws to fix the base on an optional mast or tripod, the antenna interface, in fact a small plastic box that I opened to discover it was flooded with &#65533; black gelatin &#65533;, so a true black box working as amplifier on which it was written &#65533; antenna &#65533; on one side and &#65533; receiver &#65533; on the other side from which run a small coax RG58C ended with a PL-259 connector. The interface had also to be connected to an external power supply for which only the jack was supplied. Although this material looks fine and use quality components this is however a kit for amateur : BNC and RG58C coax are not known to be the best components we can find in a ham shack. Anyway, if all that works I will be already happy. The &#65533; manual &#65533; explanations were minimalist and from what I seen the technical sheet was &#65533; compatible &#65533; with all magnetic loops sold by Wellbrook, including the outdoor and emission models (ALA 1530, etc). So I took the risk to &#65533; adapt &#65533; the graphic to my ALA 330 model, assemblying all parts according what I see on this unconventional and unappropriated user manual.

As expected I encounted my first problem : there were no connectors antenna side, nor power supply, what is a pity for what these components cost (21 euros vs the 140 euros that cost the antenna). So I still wonder why the manufacturer didn't include these parts in the kit ?! So in the next hour I had to buy the required accessories : 2 male BNC connectors, 8m of RG58C 50 ohm coaxial to feed it and a stabilized power supply 220/12V 400mA or higher with several extractible jacks to the nearest electronic shop. Hopefully the antenna interface came with a fuse (315 mA) and as I told with a short coax ended with a PL-259 connector I can immediately connect to my RTX antenna input, beside my long wire input that was always connected to compare signals received by both antennas.
Very excited, after have assemblied the two BNC both end of the 50 ohm coax and made a small welding on the screws to be sure the BNC were well

attached, connected the power supply, a few minuts later I posed the loop on front of the window, 1m high, street side. See some pics on http://www.astrosurf.com/lombry/qsl-330.htm

With its 1m of diameter the loop is rather cumbersome but as it is very light - it is made of aluminium - it was easy to place behind the veils or anywhere else, the manufacturer suggesting to place it at ground level. I switched on my Kenwood TS-570D anywhere in the bands where I could capture an emission. I also remembered the warning of the manufacturer : never use the ALA 330 in emission or I should experiment some hardware damage. But I didn't understand why I couldn't use it in emission until I questioned an OM : in fact the small transistors located in the interface will not support the 100 W emitted by the TX and will explode the system. OK, sworn, I will never use it for emission !
First I controled the signal coming from the longwire attached to the ANT1 input. Whoaw, 59+20 dB. Great ! That was exactly the kind of signal I needed to check at first if the loop was able to capture the most powerful stations located a few thousands km away from LX (G, OZ, I, EA). I switched to the loop on the ANT2 input : I heard shuffle, and that sound like if OM spoke in a pipeline. After investigation I udnerstood that the receiver worked as if the loop was not connected.. What was the matter ?
I checked for another strong signal on another band. Same problem : shuffle but nearly no station. Something was problem wrong. So I checked the interface inputs. I disconnect the fuse, then the power supply, then the antenna : I had always the same signal, □ the pipeline sound □.In fact my loop with disconnected from the system ! I probably experimented a short-circuit somewhere in the system. I reread the so-called manual that suggested some procedures of troubleshooting. I was reassured knowing now that I could experiment some problems. and probably solve them. In the order Wellbrook suggested to check the fuse, the power supply, the coax and the antenna interface.
As I haven't had at that moment any multimeter to measure my devices, I visited an OM friend of mine that helped me to diagnostic the problems. And as expected having had to build all accessories of my own and having no tool to test my components, I experimented nearly all problems in once : the interface was connected to the +12V in place of the -12V due to the fact that the power supply provided several jacks without indication of polarities, that connexion probably activated the fuse that interrupted the link with the mains. So at first I inverted the power supply jack and marked its position permanently in order that the interne pin of the interface BNC connector receives -12V. Then my BNC wire experimented a short-circuit and I had to rebuild one of the connector. This time I made the welding a bit larger on the screw as the previous one cut by itself. Having well learnt the lesson, I bough a small analog multimeter, some □ croco grips □ and once all connexions completed I rechecked all my components, from the fuse to the BNC including the power supply, successfully this time. Time lost, including the buy of accessories, 3 hours.

Lesson to learn : If you are a novice in electronics, do buy a small multimeter, ask an expert to explain you how it works, and use it to test

all electrical components you made before to use them.

Once the loop placed near the window I did various test : I changed its position in the living room, I posed it on the ground, more or less near or far from the concrete walls and I changed its orientation related to the signals. I used it at night and at noon, in nearly all my working conditions, under all kinds of QRM and up to know only by clear and dry weather (not wet nor rainy).
After some days of practice what can I conclude ? In one word I can say this ALA 330 is useful compared to my longwire flooded in QRM. I prefer to not say very useful for several reasons explained hereunder. However my appreciation is very positive in regards on its performances vs the space it requires.

Results in the field
Without having the possibility to test the antenna with a spectrum analyser I can only test the audio performance of the loop on stations or beacons I heard on bands using the loop indoor.
First the SWR. Wellbrook states the ALA 330 has no SWR. The impedance matching is not required but when I activated my TS-570D antenna tuner I heard the system selfs working a few seconds (no more than about 5 sec) and as switch from one band to another they matched successfully all bands, including WARC to 1:1, excepting the 40 m where I stopped the system at 1.5 :1 as it seemed not be able to match that rate. That was a first surprise as my short long wire (the sloper) had difficulties to match some bands below 1.5 :1 or even 3 :1 sometimes (my 40m longwire tied 3-5m high had also some problems on some WARC bands).

The antenna position. I move the loop in various places in the living room, near or far from the walls or from the window located street side but quiet (the windows is about 3m long, 1 m high made of a wood frame). When I placed the loop on the ground, under the window, in front of the radiator turned off, the QRM increased a bit (1 point) and disappeared when I placed the loop back just in front of the window, at 1m high and behind the veils. The fact to move the loop near or far from the concrete walls did not change anything to the signal or QRM level, as changing its orientation from vertical to horizontal or to tilt it at 45 deg, or changing its orientation in regards with NSEW positions, nothing changed the signals or the QRM intensity.

So I can already conclude that this ALA 330 is not sensible to its position vs the signals but well to the distance to concrete or maybe to dense objects.

I also made a test installing the loop in the cellar, what means in a room under ground level made of concrete all parts, which walls are not more tick than the one of the appartment. Amazingly, I continued to listen stations with nearly the same intensity as at the second floor.

At last the stations signals. The signals are globally stronger with less QRM using the loop than vs my longwire sloper, mainly in bands from 17 to 10 m with the best noise reduction in the 17m and 12m bands where the QRM

dropped from S-9 to as small as S-1 ! For the first time for many weeks I could hear in LX stations that were flooded previously in the QRM.

As strange as unexpected on the 20, 40 and 80m band, the loop captures the same (on 20 m) or, at night, even a bit more QRM than my longwire. I cannot explain this phenoma. The S-meter stays at the a same level of intensity on both antennas (sometime 1 point up with the longwire) but even at equal intensity on the S-meter my ears capture a noisier QRM with the loop than with the longwire.

In the 160m band, where the loop is theoretically not adapted, the QRM is also a bit lower with the loop but this band was nearly free of OM at the time of my tests and I checked the signals intensity with beacons.

Here are some figures I recorded at noon and at midnight. Know that my village is located in the country, 7 km south from Luxembourg city (Yes indeed, at 7 km from the center of Luxembourg this is the country !), which capitale is surely not as strong QRM generator as could be a megapole like New York, London, Paris, Melbourne or even Brussels (all the country gathers about 400000 inhabitants) but it could be if the QRM generator is one floor up ! For each frequency I displayed 2 values : the intensity of QRM and the one of a OM in QSO or the beacon. Signals were captured with the 35m longwire (located 60% indoor and 40% outdoor as a sloper) and with the magnetic loop placed in front of a window 3m long of the living room located at the second floor on my appartment:

At noon (12z) :
29.5 MHz ,QRM Longwire 57, Station signal, none, QRM ALA330, 54, Station signal 55
28.5 MHz ,QRM Longwire 56, Station signal, none, QRM ALA330, 51, Station signal 56+
24.9 MHz ,QRM Longwire 59, Station signal, 58-59, QRM ALA330, 57, Station signal 58
21.3 MHz ,QRM Longwire 58, Station signal, 57, QRM ALA330, 55, Station signal 57
18.1 MHz ,QRM Longwire 58, Station signal, none, QRM ALA330, 54, Station signal 56
14.2 MHz ,QRM Longwire 57, Station signal, 57-59+, QRM ALA330, 57+, Station signal 58-59+
10.1 MHz ,QRM Longwire 57/57, Station signal, 59+10, QRM ALA330, 54/56, Station signal 58
7.05 MHz ,QRM Longwire 57/58, Station signal, 59, QRM ALA330, 57/57+, Station signal 58
3.7 MHz ,QRM Longwire 57/55, Station signal, none/57, QRM ALA330, 55/55, Station signal none/59
1.9 MHz ,QRM Longwire 59+10/57, Station signal, none, QRM ALA330, 58/51, Station signal none

At night (32z):
29.5 MHz ,QRM Longwire 56-58, Station signal, none, QRM ALA330, 51-53, Station signal none
28.5 MHz ,QRM Longwire 57, Station signal, none, QRM ALA330, 51-53, Station

signal none
24.9 MHz ,QRM Longwire 58, Station signal, none, QRM ALA330, 56+, Station signal none
18.1 MHz ,QRM Longwire 57/58, Station signal, none, QRM ALA330, 55/51, Station signal 54/53
14.2 MHz ,QRM Longwire 57/55, Station signal, 57+/58, QRM ALA330, 56/55, Station signal 57/58
10.1 MHz ,QRM Longwire 58, Station signal, 58, QRM ALA330, 57, Station signal 59
7.05 MHz ,QRM Longwire 57/57, Station signal, 59/58+, QRM ALA330, 53/56, Station signal 55/58
3.7 MHz ,QRM Longwire 56, Station signal, 58, QRM ALA330, 57, Station signal 59
1.9 MHz ,QRM Longwire 59+, Station signal, none, QRM ALA330, 57, Station signal 53

During these quick tests I was able to hear KL7 and JA stations, even if the first arrived weakly. The result is thus positive.

By way of conclusion
Plus of ALA 330 :
- Reduces drastically QRM over 7 points in 17m to 10m bands, much less useful in the lower bands at night
- Sensible QRM reduction in 160m (QRM drop of 1 point).
- theoretically request no antenna tuner for matching impedances
- Very light antenna, not combersome compared to any passive antenna
- Quality of assembly kit
- Easy to assembly and installed indoor in a few minuts
- Not too expensive in regards of its performances
- Suited for LW and HF listenings
- Highly recommended when space is limited
- Good support from the manufacturer

Minus of ALA 330 :
- Add 1 more point of QRM in 40 m bands, no improvement in 20 m. - User manual unappropriated, lack of technical advices (on paper of on website) for the beginner
- For a novice user, basic accessories missing (BNC, power supply) with risk of errors when assembly the parts.

Should I place another order if needed ? Surely. But I should probably buy a more sensitive model if available. But more important I should change all cabling system and connectors with ham approved parts : BNC with PL connectors (or an adaptor BNC/PL) and the RG58C coax with a RG213U 50 ohms coax, in order to reduce the signals attenuation, losses in the cable and still a bit more QRM.
I could already change all these components in the current installation but let me rest a bit a few weeks after have worked hard to make this installation running ;-)
However this is not a joke. I seriously think that changing all parts with professional components - excepting the loop - I could still improve

quite a lot the reception.

At last a test will be performed in my second QTH to compare the performances of the loop vs my 40m longwire tied 3-5m high on tops of hills at W�pion, Belgium. I'm not sure that the loop will improve the signals. In the opposite case the magnetic loop will surprise me. To be followed in a future post (as an addendum to this one if it is always online at the time of this 2d test).

For more information
The ALA 330 as well as other loop antennas suited for emission can be obtained from Wellbrook Communications, Wellbrook House, Brookside Road, Bransgore, Christchurch, Dorset, BH23 8NA, U.K.
Phone: 01425 674 174, International : 44 1425 674 174
Website: http://www.wellbrook.uk.com/
The current configuration cost �112.5 or 178.04 euros. Cmpleted with all requested accessories (power supply, BNC and wire) it cost about 200 euros.

Hope this helps.

Hi,

It seems that when the diameter of a dipole antenna (or any antenna) gets
thicker, the antenna becomes more broadband.

What is the explaination of this fenomena?
And can it be proven mathematicaly?

Or where can I find some explanation on the internet or books?

thanks Peter

From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <amhlknipe1@helle.btinternet.com>
Source record: 134367

If insulated radials are laid on the soil surface, no difference in loss resistance at all.

If insulated radials are buried then resistance DECREASES in series with a capacitance.

The series capacitance is of no consequence because it is tuned-out by the tuner along with the antenna reactance.

Reduction in resistance depends on thickness of insulation.

For enamel and thin plastic insulation the decrease in resistance is small and in practice is not noticeable.

For thick insulation, such as the inner conductor of a coaxial line plus 1-inch diameter polyethylene, the resistance increase might be considerable. It is calculable. No-one would actually do this of course. It's too expensive. Better to lay one or two ordinary extra wires.

From the number of times this question is asked, this little snippet of info could perhaps be mentioned in the handbooks.

From the ARRL Antenna Book, 15th edition: "... the reactance varies at
a different rate with frequency changes for different wavelength/diameter
(ratios for the) elements. In other words, looking at the two (different)
element (diameters), the Q's are different."

> And can it be proven mathematicaly?

If the reactance around resonance of two antennas changes at a different
rate with frequency, the bandwidths will be different. That is easily
proven mathematically.

Hi Richard,

I had an excellent demonstration of the physical equivalent to this yesterday at a local electronics vendor (Radar Electric in Seattle).

I was intrigued by their attempt to sell foot long aluminum pipes as magic wands. In looking over the merchandise (you can imagine how long that took), I was approached by the store manager who wanted to close a sale (I am sure he was dubious of this prospect however).

He asked if I knew what it was used for. I speculated "as a torque extender?" He smiled and lifted a spherical magnet off the nearby display and plunked it into one of the tubes. It should have dropped straight to the floor in a heartbeat (or so the first impression would have been), but he calmly lowered his hand to the bottom of the tube and waited for the sphere to emerge - quite slowly.

"See? Magic! And this is aluminum, not steel!"

"Bucking fields induced by the eddy current generated by the fall of the magnet." I quipped back.

He shrugged his shoulders and muttered good humoredly about engineers killing his wallet.

The skin effect experiment has similarly been a no-sale - and far less magic.

You can also build UNTUNED loops which, obviously, don't need any tuning.
Check out
http://www.lwca.org/ for links to some design and construction info on
tuned and untuned loops.

==========

As the diameter of the antenna conductor increases so does the capacitance per unit length and the inductance decreases. It constitutes a tuned circuit with a damping resistance equal to the antenna's radiation resistance.

Fo a 1/4-wave vertical or a 1/2-wave dipole calculations simplify to -

Q = 1.29 * [Ln(Lambda / 2 / d) - 1]

where Lambda = free-space wavelength and d is conductor diameter, both in metres.

Naperian logs.

Bandwidth follows from elementary tuned circuit theory.

The formula is approximate (but adequate for anything) because radiation resistance varies somewhat in the vicinity of resonance and dependence on antenna height is ignored.

==========

The above shows antenna Q decreases VERY slowly with conductor diameter. At HF it needs a cage antenna to have an appreciable effect. And since system bandwidth may depend as much on transmission line and tuner characteristics (never considered in connection with system bandwidth but both are tuned circuits) by itself the formula is not of much value.

For calculating some characteristics of a dipole versus diameter, including bandwidth vs SWR, download program DIPCAGE1 from website below. Takes only a few seconds. Run imediately.

Good quality mechanical laboratory balances use magnetic damping --
simply an aluminum plate on the balance arm that fits closely between
the poles of a magnet mounted on the fixed portion. Same principle.

Peter Tribout wrote:
"What is the explanation (the thicker antenna is more broadband)---?"

The average surge impedance on a fat wire antenna is lower than on a thin wire. Voltage is lower on a fat conductor for a given power because charge is distributed over a larger area.

Radiation resistance and Q are lower for a fat wire, and at frequencies ABOVE first resonance, they oscillate around reasonable values at a dipole`s feedpoint. Excursions are much greater for the thin wire.

The details of proof and explanation are tedious, but they can be found in Arnold B. Bailey`s "TV And Other Receiving Antennas".

Hi OM,

That may well be, but there are many here who can manage foreign
traffic quite well.

For those less fluent there is always AltaVista:
http://babelfish.altavista.com/tr
which provides a simple resolution:

"I seek experiments of OM which emit with a magnetic circular antenna
of mark BABY LOOP manufactured by an Italian company. Apparently this
antenna compared to those described in the articles of "construction"
and those of MFJ (1786, 1788...) would have a directivity not only
before side of about 25 dB but also a directivity front compared to
the back of 7 dB. I will wish to have confirmation of that because
this directivity before back allows in theory a use starting from the
window without "irradiating" the dwelling. Moreover I would wish to be
informed of the experiments of the users of this antenna, namely: ï¿½les
installation requirements, ï¿½dans the case of a use on balcony
embarrassment TVI exists it for the neighbor of the lower part? Which
are the configurations to be avoided? ï¿½le adjustment of the antenna
using the CV ordered by engine is it easy with the case of basic
command or is worth it better from the start invest in the case of
order with automatic tuner? Can one with the case of basic command, to
establish according to the frequency used a curve position CV =
F(frï¿½quence). Is the automatic tuner it really a truth limps of
coupling? ï¿½ce standard of antenna really makes it possible it to
practise an activity of radio ham? Which are the most suitable
frequency bands? With the advance thank you of all this information"

Not having any experience with small loops, I had nothing to offer.

Hi Richard,
anyone interested in this can do a search on Lenz's law,
or,
better yet, read an undergraduate physics text, which, if any good, will go into more detail on how Lenz's law works. (If you read Feynman, he calls it Lenz's rule.)

Hi Peter,

When you dig into the origins of the math for dipoles, you will find
they derived from the form known as the biconical dipole.

The biconical dipole appears as two cones whose tips are converging to
the feedpoint; and through their geometry present a radiator of
constant line properties. The flat characteristic translates into
broadbandedness and the "fatness" of the radiator is evident.

You can also think of a "fat" radiator as simply being a bloated
cylinder. That works too, but the biconical math is much simpler, and
is the basis of everything else. The cousin of the biconical dipole
is the conical monopole, or the more familiar discone.

I'd get one of those halfwave rubber duck antennas for ht's, and mount it somewhere. Doesn't require a ground plane to function, and the rubber duck "should" be fairly safe if you wreck and stick one in your gizzard some way. MK

Dear Roy,

No measured data needed to support description of an effect which is intuitively rather obvious and can easily be estimated by calculation in a practical case.

I would have thought you would know how to perform the calculation. Can't you find how in your reference library ? How about Terman ?

A dipole fed with coax on 80m is pretty much unbeatable by any equal length wire antenna. But, alas, not very multibandable. I guess the ladder line/tuner the next best thing. Nothing wrong with the ladder line, but the tuner will add a little loss, and usually the antenna will slightly lose against the coax fed dipole. Myself, I'm too hard core to ever consider a windom or G5RV on 80m. I've tried both, and they were below par for my standards. Normally, nothing but coax fed dipoles for me on 80m. The only time I use my tuner is on the attic 40m dipole fed with twin lead. MK

Source record: 134287

I don't think my last post on this made it to the list.

With the trombone cap I designed, it looks like my loop can just about make it to the bottom of the phone portion of 80 meters.

I was going to add just a little to the loop to get it the whole way there.

But I noticed that the BW was pretty narrow, 1.2 kHz @ 3.750 mHz.

Questions:

Just what is the effect on a SSB signal at such a BW? Will it freak out the transmitter?

Does the BW get a little wider with losses in the antenna system than predicted? In which case, I'm worried about nothing.

George, can't reply to your e-mail about S-meter calibration.
My replies bounce back. But not to waste my hard work I repeat it here.

It has no meaning to attempt to qualify S-meter indications with 0-Peak, Peak-to-Peak, RMS, etc.

The receiver-plus-S-meter is basically a watt-meter. It is a receiver input power meter. It could be scaled 0 to 1 milli-watts or in decibels relative to 1 milli-watt. This allows receiver input power to be compared directly with transmitter radiated output power.

If the transmitter output is described as peak power then the S-meter can only be assumed to indicate peak power. The receiver has no way of knowing what the Tx modulating waveform is and receiver gain does not change with the transmitter's modulating waveform.

It is conventional, of course, for the scale to marked in decibels relative to 50 micro-volts across 50 ohms (= 50 pico-watts = S9). That is if the receiver input is 50 ohms.

Each S-unit below S9 corresponds to a 6 dB reduction in input power.

It should be noted that some form of matching transformer to match a high impedance receiver to a low Z antenna has no effect on measured Rx input power or on the meter indication.

The ability of the S-meter and its de-modulating circuit to respond or not be responsive to voltage waveform is not relevant. THAT problem applies to SWR/Power meters and depends on how hard the operator screams into the mike, male or female voices, etc.

To reduce frequency just add a lump of high-voltage fixed capacitance across the variable C.

As frequency decreases radiation resistance gets smaller, Q gets higher and bandwith gets smaller.

So the transmitter behaves as when followed by a narrow band filter.

It has a similar effect on audio as a narrow band crystal IF filter does in the receiver.

The effect on the transmitter must be extremely complicated. But it would appear it is not severe enough to affect the life of PA transistors. I've run 160m magloops at max Tx output with no problems. Never had any reports of poor audio quality.

Presumably the SWR-controlled ALC looks after things in the normal manner.

Reg, G4FGQ

5450. Re: Follow-up Disk Skin Effect Experiment

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-21 20:42:14 UTC
From: rsparks <rsparks@elltel.net>
Message-ID: <3d8cd5b9_1@corp.newsgroups.com>
Source record: 134291

In both disk experiments, the measurements did not show that the disk added inductance to the circuit.

Could this be because in both cases the applied current flows radially from the center of the disk due to skin effect? However the induced current below the metal surface flows the opposite way so the induced current would have no place to go. In other words, the induced current would flow to the center from all radial directions but would not have a circular path within the conductor. Without a circular path, the induced current would stop and the applied field (causing the induced current) would not be fully canceled. In this respect the disk would be similar to the Faraday Shield.

If the applied field is not fully canceled, it will continue through the disk to the far side where conditions are again correct to allow an induced current to flow. The far side of the disk has another wire attached so the induced currents can flow radially to the center and away on the attached wire.

Now the induced current (now located on the far side of the disk) and the applied current (located on the near side of the disk) still must complete to have a continuous circuit. If the current went all the way around the edge of the disk, it would take wave travel time to fully complete, so we should have inductance.

On the other hand, if the electrical field passed through as easily as the magnetic field, then the current could encounter a capacity effect between surfaces. This would be a result of the slow travel rate of the charges through the metal. We could think of it as a situation where the presence of a charge on one surface would "bump" a charge loose on the other surface.

A combination of these two effects would result in the current passing through the disk as if the disk were a low impedance capacitor. That was the conclusion I reached from the data from the first disk antenna experiment. I did not understand how that could occur when I ran the experiment. Now I think I have a logical explanation.

In summary, when the time varying current arrives at one side of the disk, it spreads radially along the disk surface. The current makes it's 'presence' known by creating an electrical and magnetic field that generates an induced radial current deeper into the disk. The induced radial current all flows towards (or away) from the center which is bounded by more metal so it can not flow at the magnitude which is required to fully cancel the applied fields. The applied fields (which are only partially canceled by the restricted induced current) pass to the far surface where they are able to induce a current that will flow radially to the center and away on the attached wire. The applied fields are completely canceled by the fields

from the induced current on the far side of the disk.

So what do you think?

5453. What vertical and how to fix it : HF9V, R9,...

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-21 21:15:59 UTC
From: lombryt@hotmail.com
Message-ID: <db35a0c.0209211315.cc491a2@posting.google.com>
Source record: 134294

Hi,

I know that the question was partly asked many times but even after have read the reviews of ehams and several long post on this forum, I haven't found an complete answer as many post shift at the end to others considerations.

As SWL I'm currently using a 40m long wire in one QTH and an ALA 330 magnetic loop (see my review today) on another one.

With time I think seriously to replace my long wire tied 3-5m up in the garden - that give me however excellent results for what it cost and represents -, with a "true" antenna to gain some dB (not difficult vs a longwire !) and made more DX, my first activity.
I prefer to avoid beams as I will rotate it every minut to capture any interesting DX and I will probably finally burned its rotor, as heavy it could be. So a serious all HF bands vertical (at least 10 to 80 including WARC) will most than probably satisfy my needs. But what model of all bands vertical ?

For the moment (that could change) the price is not a concern, so I can pay up to $500 (I would not) if it is really necessary and if I decide to no more waste my money !

I think especially to a HF9V from Butternut (2d choice) of a R9 from crushcraft (there is no more R7 I think) or any other similar one. Is there another brand that sales top verticals ?

I'm however afraid of the potentiel trouble I could experiment in assemblying or "matching" Z and SWR of these verticals. I read e.g. that some OM were in trouble with the traps of the R9, or with the soil conductivity, etc.

So my questions are more practical.
Question 1: what vertical should be easy to install for an novice ? (I can always find an experimented OM if needed of course - I hope).
For a little handyman like me who can hardly read a multimeter (just to test my wires or components), has never build or assembly an antenna (my loop is nearly pre-assembled) or who doesn't take the time to read manuals !, is there a vertical easy to install, to troubleshoot, for which there is a true support from the manufacturer or dealers and that has exprimented very few trouble with its traps, radials or counterpoises and able to support quite strong winds, and endly that can survive some (dozen) years ?

NB. The vertical should be installed in the backyard near a group of trees, on top of hills where the winds may blow up to over 100 km/h a

few days a year and which soil is mainly rocky a few dozen cm deep.

Question 2 about the vertical itself :
The R9 looks more simple to assembly but some OM experimented problems, HF9V looks hard to assembly, looks more cumbersome and request optional kits to work properly (kit of radials, etc). About the others brands, no information. So what could be the simpliest installation (what model) requesting the less servicing and supporting the best any wind (I think specially to model in new material, carbon, etc, that are flexible).

Question 3 about the vertical attachment:
The vertical should be attached by its short base - 50cm to 1m long I hope - with 4 or more large "rings" (so much as necessary) to the small support mast currently supporting the linen wires as it is in metal and well burried deep into the ground (see a pic of the linen wire on my website, http://www.astrosurf.com/lombry/qsl-longwire.htm). This short mast in shape of "T" can bend a few cm if I push hardly on it with all my 65 kg (!) but seems able to support such "light" antenna....
Otherwhise I should attach it on the back of a cottage (made of wood) located at the end of the garden, but it is still 20m more far from the shack than the mast.
Is the concerned small green mast sufficiently robust or surely not to support a 6 kg vertical 7m high by soft or strong wind ? Do I absolutely need to reinforce the vertical by hardly attach it with cables tied in 3 or 4 points at ground level or it can bend slightly of a few cm without problems under bad weather conditions (they are no hurricane in that QTH) ?
Are the fixations to the walls of the cottage the only other solution to prevent any break of the vertical (I think it is, because it is more sheltered from strong winds influence due to nearby high trees), but here the distance to the shack request probably a RG213U coax and nearby high trees could maybe interfere with signals...

All your comments are welcome about the model of vertical to buy and its fixation in regards of what is currently available (small mast or cottage).

Thanks for comments.

According to the Guinness Book of Records, some years back, the record holder was based on this complaint:

"What did you bring that book I didn't want to be read to out of about Down Under up for?" (However, my late father, pedantic English teacher that he was, pointed out that "Down Under" is a noun, not two prepositions.)

(If you must spam me, replace "Earth Wolf" with 'aardwolf')

In accordance with a first aspect of the present invention, there is provided a transportation facilitation device including a circular rim, a bearing in which a hollow cylindrical member is rotatable about a rod situated within the hollow cylindrical member, and a series of connecting members connecting the circular rim with the hollow cylindrical

member to maintain the circular rim and the hollow cylindrical member in substantially fixed relation, wherein the rod is positioned on an axis perpendicular to the plane of the circular rim, and substantially central of the circular rim.

Abstract from John Keogh's successful 2001 application for an Australian patent (Innovation Patent #2001100012) for the "Circular transportation facilitation device" aka "wheel".

Hi Ian,

The term is usually used to describe a structure made of wires arranged radially around the coax. The wires are usually 1/4 wave length long, but may be shorter if the structure is so close to ground that the wires are detuned by ground proximity.

The idea is that the structure is at very low RF voltage at the center for the design frequency.

Randy, I can't speak for everyone, but where I live there are cc&r's that restrict antennas. I moved in
18 years ago. Got involved with amateur radio 16 months ago. When I moved in, I had no idea I would
ever want an antenna, so it didn't bother me. Hell, it could have said no hippopotamus's allowed,
because I don't expect to own one of those either.

I can't afford to move somewhere else. So, what should I do? I do what I can to be unobtrusive and
stealthy. so far,no problems. But, I do get tired of hearing "why did you move in there?" No offense
intended to you, but it does happen that way.

==========

Mike and other passers-by,

For given loop dimensions, the lump of extra fixed capacitance needed to decrease frequency to the next lower band is obtained immediately from program MAGLOOP4. (And the earlier loop programs.). As also is the loss in efficiency due to lower radiation resistance and the corresponding S-units. Unavailabilty of the highest frequency bands due to lumped C can also be deduced. Unfortuately, due to the very large loop current, lumped C cannot be connected/disconnected using alligator clips - a melt-down could occur in the clips. ;o) But when experimenting with extra capacitors temporary alligator clips are OK at reduced power. I have had my fingers burned when changing bands even when the transmitter is off. It takes time for the

clips to cool off.

While on the subject of joints in copper water-pipe magloops, the popular misconception plagiarised and propagated by old-wives' that soldered elbow joints are something to be avoided like the bubonic plague is a load of nonsense. Just don't smear the solder over the external copper surface any more than necessary to form a sound mechanical joint. Just re-heat joints and wipe off all surplus solder.

Bright, new, polished copper has an attractive appearance. Paint the finished loop with clear ship's varnish and it will stay that way. The next-door neighbors peering over the garden fence will love it.

A magloop has greater efficiency than any other form of antenna construction of the same greatest overall dimension when the dimension, eg., loop diameter, is only a small fraction of a wavelength. It is a several-band antenna.

A magloop also has the very useful property that the diameter of the small matching loop tends to be independent of operating frequency. It is not analytically proven so - it just so happens when height of the bottom of the loop above ground is as usually installed, one or diameters above ground level.

So very likely it may not need a tuner on all bands it is desired to be used with. Coupling to the feedline is effected by adjusting the diameter of the coupling loop which is best left as an unshielded length of self-supported of wire which may be of no greater wire diameter than the inner conductor of the coaxial line which feeds it. There should be as small as possible RF connection between the main and coupling loops. Delta-match and other feed arrangements should be avoided as these encourage radiation from the coaxial feedline. Radiation from the feedline upsets the null on receive. If the antenna is rotatable a sharp receiving null is a valuable asset.

The geatest disadvantage of small magloops is the cost of a slow-motion, motor-driven, high-voltage, high capacitance tuning capacitors. But for single-band working most of the tuning capacitance can be lumped and a hand-operated small trimming capacitor can be considered. Again, the various options can be studied by using program MAGLOOP4.

I've a feeling I have something else to say but the onset of Altzeimer's desease is having it's effects.

Oh yes - I have forced myself to recall. I have no shares or any other sort of interests in any manufacturing company, least of all in the manufacture of magloops, motor-driven capacitors or automatic antenna uners - or even copper-water-pipe sellers.

Good night to all.

Bottom line is, if you learn about, and become involved in, ham radio only after you move into a CC&R property, you will be required to move in order to actively pursue it in an effective, unobstructed way. That clearly and seriously impedes your ability to use ham radio as an emergency communications asset, one of the primary purposes of its existence. That fact alone should be sufficient grounds to qualify for legislative relief.
No one suggests that all hams should be free to use whatever antenna they wish under those circumstances. But reasonable accommodation is clearly justified and in order.

Dick

Having had a little experience at soldering copper plumbing when I plumbed my own new house many years ago, I think there may be some realistic basis for those high resistance tales. If one doesn't properly prepare a copper pipe joint before soldering, the solder won't adhere properly to both pieces of pipe, and you will get leaks in your plumbing, or higher joint resistances in your magloop.

What I learned from an experienced plumber before I took on the house plumbing job was to thoroughly clean both the inside of the pipe that the other piece will go into and the outside of it, as well. Use either fine emery cloth or fine grain sand paper, and scrub all surfaces bright. Then thoroughly away the residue with a clean soft cloth. Then, when the joint is properly prepared, use a good quality soldering flux on both pieces.

Your joints will not leak nor be of high resistance.

Roger, W7WKB wrote:
"(the current) spreads radially along the disk surface."

Roger has it! The current is alternately being dispersed and collected by the wires on either side of the disk. The current, as one poster put it, is running as an ant would run (some ant moving nearly at the speed of light!). The ant takes the shortest distance between the wires via the surface of the disk.

Current between the two sides of the disk tends to srpread through the entire 360 degrees around the disk due to the homophobic nature of the charges. These creatures repel each other. At the edge of the disk, these charges just climb around the edge and maintain as much spread as they can while congregating toward the far wire terminal. At 1 Mhz, these fellows aren`t venturing deeply into the copper surface, for the most part. The higher the frequency the less venturesome these creatures are and the less they penetrate the copper. At 1 MHz, skin depth is between 2 and 3 thousandths of an inch in copper. The charges must travel in a length of only about 2 disk radii between wire terminals.

Recall that the cause of skin effect is supposed to be increasing inductive reactance deeper in the metal, so current flows on the path of less opposition and that is the surface.

Recall that the resistance per square on this surface is so low that it faces extinction.

Inductance tumbles as conductors get fat. It`s the skinny wire that raises inductive opposition to current flow. Roger`s disks are fat bumps in the wire.

Capacitance between sides of the disks is made irrelevant by the short circuits around the disk edges. Capacitive coupling doesn`t make an appearance between the inside and outside of a well shielded box, so it doesn`t allow escape of the energy contained within the box. It also keeps energy on the outside of the box excluded from the inside of the box.

Radial current on the disk does produce magnetic lines which engulf the disk, but the flux on one side of the disk tends to negate flux produced by the other siide. The currents which produce them are flowing in opposite directions. Also, counter-emf on both sides of the disk tends to cancel the imposed field on its own side.

Conclusion is that conduction provides the best coupling of the disk sides. Voltage drop is instantaneous and in sync with the current in a resistance (conductance). The only delay is the wave transit time from

one wire terminal on the disk to the other disk wire terminal. The wave is moving at almost the speed of light on the disk. The disk dimensions are small in terms of wavelength so that the effect of the disks is inconsequential. Roger`s experiment indicates that effects of the disks are inconsequential.

Best regards, Richard Harrison, KB5WZI

==========

Mike, you have hit the nail right on the head ! I feel I can let myself loose

With the kindest of hopefully constructive criticism, and with the assistance of 3/4 bottle of Sicilian white, it is the handbooks and newsgroup contributions by Guru's which cause the unnecessary, confusing complications.

KISS

Contributing Guru's do not fully understand what it is people really want to know. In general, between them, they do not lack practical experience or theoretical knowledge. Rather that they do not have sufficient ability to express themselves unambiguously in terms which questioners understand. They are unable to put themselves into the minds of readers although in their earlier careers they probably passed through such learning stages.

There's too much dependence on references to somebody else's past work. Such references being similarly based, with nothing added in the propagation process except to ego's. Education suffers. After all, the purpose of amateur radio is to facilitate and promote self-education in the arts of radio communications. That's from where the pleasure, satisfaction and international social relationships are derived.

Over the last few years it has been suggested I am a Guru myself. Usually in the derogatory sense. But I always consider it to be a sort of back-handed compliment. On the other hand I consider myself not as a Guru but an Iconoclast - a cast-downer of unjustifiable idols !

Having got that partially guilty, public self-examination off my chest I can now finish the remaining quarter-bottle and retire to bed.

Very true, Dick. I've done a bit of homebrew plumbing, aside from my
electronics soldering experience. And I've made a few bad plumbing
solder joints. NOTHING like having to drain pipes and redo a bad joint
to teach you respect for doing it the right way.

Well, I cut the pipes and soldered the antenna together in my driveway
this evening. Everything went well, but I think my neighbors must think
I'm mad. Funny to watch them come home and watch me; trying to guess
what I'm up to now.

A counterpoise gives the differential current a place to flow from/to.
When it is flowing into the antenna, it is flowing out of the counterpoise
and vice versa. A counterpoise can be as simple as an electrode in salt
water or a single 1/4WL "radial". It can be as complicated as 100+ radials
buried in the ground. Some have tried an 8 ft. ground rod as a counterpoise
when feeding a 1/4WL vertical monopole mostly with unsatisfactory results.

Reg, G4FGQ wrote:
"How about Terman?"

Terman actually does have something to say about reactance and resistivity in the earth`s surface including the following:
"At broadcast and lower frequencies, the ratio of capacitive reactance to earth resistivity is considerably greater than unity so to a first approximation the earth can be regarded as purely resistive."

Also:
"conversely at frequencies of the order of 10 MHz and greater, the impedance represented by ground (but not sea water) is primarily capacitive---."

Terman says conductivity of the soil controls ground propagation at medium wave frequencies and lower but somewhere below 10 MHz, soil resistance is bypassed effectively by capacitance so we can forget resistivity in real earth at these higher frequencies.

For fun I estimated the capacitance to earth of a plastic insulated wire 250 ft. long as 0.001 microfarad. This would have a reactance at 1MHz of 160 ohms.

Over a half century ago we used 20 ohms as the resistance of the soil between any two points for many types of problems involving low and medium frequencies. It wasn`t important to get answers applicable or representative of anything. It was only for practice in using various methods.

But if 160 ohms for the reactance of the radial`s earth connection, and the resistivity per square of 20 ohms for the earth were representative, I would rather use a bare radial at 1 MHz. At 10 MHz, there would be very little advantage to using a bare wire.

Best regards, Richard Harrison, KB5WZI

Hi all,

I'm trying to construct an antenna for my transmitter / receiver system. I got a copper wire cut to about 31 inches. I'm planning on putting it on top of a base insulator that is about 2 inches high from the ground plane. My ground plane will have a diameter of about 8 inches.

I'm trying to figure out a way to measure the capacitance of the antenna. How would I do this? I'm operating at 15 MHz.

My problem is basically getting a clear understanding of physical antenna length versus electrical length. From what I've gathered, antenna length should be some multiple of the wavelength. However, physical length does not matter that much compared to electrical length.

The reason why I want to know the capacitance is so that I can find a value for my inductor that will enable me to create a resonance at 15 MHz. Thanks!

Sometimes, sometimes not. I've been surprised on a number of occasions
to find hams using just that scheme and making lots of contacts. Must be
the soil or its moisture content.

I would just add the observation that the maker of the Carolina Windowm 80
does NOT recommend using it in an inverted vee formation. If you need a
vee, it probably wouldn't be a good choice.
I have one myself. It's basically an 80 dipole, and it's feed arrangement
has been designed, as a compromise, to be easily fed on all bands. Unlike
my old (no longer up) 80 meter ladder line fed dipole, it easily matches
all bands.

5482. 6 meter beam - why resonant at 52.3 AND 40.0

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-22 06:32:44 UTC
From: ehsjr@bellatlantic.net
Message-ID: <3D8D640E.A4E32B3C@bellatlantic.net>
Source record: 134173

I built a 6m 3 element beam: 3/4 dia. elements, no taper,
plumbers delight, gamma match; 112, 107, 100 spacing 48",
2" dia. boom, all aluminum.

I set up the gamma match for resonance (X = 0); R = 52
at 52.3 as measured with an MFJ 259B. The antenna was mounted
on a PVC mast in a tripod about 7' above my driveway, and aimed
at a house (through some light shrubbery) about 75' away.
The 1.7 swr points were 51.4 and 52.8.

I happened to "scan" other frequencies, and found another
resonance (X = 0); R = 50 at about 40.0 (can't remember
the exact frequency). (I found no other resonant point.)
In both cases, the SWR measured 1.0 on the analyzer, and
Xc & Xl were 0. In both cases, 50' of RG8 was used, much
of it coiled on the ground. I was standing about 10' away
off the ends of the antenna elements, and when I moved
around the analyzer readings stayed steady. When I waved
my hand about a foot in front of the director, the readings
jumped around as expected.

I'm trying to figure out why the thing has this
"double resonance" and haven't a clue.

Anyone know what's going on?

5484. Re: tower paint

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-22 12:55:13 UTC
From: Les Kramer <wa3sgz@mindspring.com>
Message-ID: <amkfesvhr1@slb4.atl.mindspring.net>
Source record: 134176

Hi Richard,

I'm a materials engineer/corrosion engineer with 32 years of professional experience so maybe I can help out the newsgroup on tower painting. Occasionally I give talks to my radio club on corrosion and the radio amateur.

First, let's remember what paint is - some kind of volatile organic binder (latex, alykd, acrylic, epoxy, etc.) with pigment (titanium oxide (white), carbon black, iron oxide (red), etc.) and proprietary compounds for corrosion resistance, rapid drying, etc.

There are two basic kinds of metal paint. Inert barrier paints that isolate the metal from the environment until scratched (i.e., Rustoleum and most other paints) and sacrificially corroding paints (Cold pack galvanize) that as previously noted is expensive. The deteriation mechanisms are different.

The single biggest reason for short paint life is surface cleanliness. As they say on the can, remove all rust and solvent clean If you really want to know if the surface is clean, take deionized or distilled water, and drop one drop with an eyedropper onto the surface to be painted. If the water drop "beads up" like on a well waxed car, then the surface is dirty even if you cannot see it. If the drop spreads, the surface is clean. Remove the water and paint after the surface has been found to be clean.

Assuming the surface is clean, then the most usual reason for paint failure is:

A.) Inert Barrier Paint (i.e., what you are most likely to buy at Home Depot)

Deterioration is most likely from UV damage alternated with moisture entrapment. If you don't believe me about UV damage, run your hand over the exterior of your house paint after a few years, and you will fine that it is chalked (in other words, the pigment is on the surface and the binder has deteriorated). The best way to stop this is to use black paint with lots of carbon black to block the UV. Obviously, this is a problem for your XYL, but for a tower it might be OK. A ham neighbor once ran clear jacket RG8X up his 100 ft. tower a few years ago and replaced it in 6 mos - same problem. Carbon black is the best thing commercially to delay UV damage.

With regard to the sand erosion claim, unless you live in a desert with high speed winds, my bet is that erosion is a third order effect in most places around the country unless the paint is really deteriorated prior to the erosion. Probably, chemical attack of the paint from air pollution is more likely. Corrosion resistant metal suppliers and paint vendors typically check their products for years in rural, marine, city, and industrial

exposure sites as well as using a bunch of accelerated anti-weathering, salt spray, and humidity cycling lab tests - usually to ASTM specs.

B.) Galvanize and Cold Pack Galvanize Paint (i.e., less good than the former) protect the underlying metal by corroding sacrificially to the steel benealth. That is why you see old galvanize with rust patches (i.e., local zinc exhaustion) rather than many rust spots - the zinc coating on the surface has a good "throwing power" to protect the underlying steel over a large area compared to an inert barrier paint will start corroding quickly at the damaged spot in the coating. Because zinc corrodes to protect the steel, it forms zinc oxide on the surface. This oxide needs to be typically removed with a mild acidic cleaner to make inert paint top coats stick to the zinc if you want to add color or a redundant coating. Cold pack galvanize on aluminum towers has the potential to be detrimental (accelerate corrosion) in some cases, so you might want to be cautious about this approach.

So--- the question is, what approach is best? Not surprisingly, the answer is "that depends". If you live by the sea, you may want to paint old galvanize with cold pack paint and the use redundant inert topcoat black paint. In a rural area without 60 MPH blowing sand, you may want to use black paint. By a fresh water lake in the midwest, you might want to us cold pack galvanize paint. In short, the answer depends on your location, typical weather, quality and quantity of the materials used, surface preparation, application methods, condition of the substrate, and a bunch of other factors that may have to be evaluated carefully first hand by a knowledgeable person in the art.

This is a long post, but I wanted to address a number of issues noted on prior messages.

73,

Les

5486. Re: 40 m dipole near Beam Mast? A Problem??

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-22 13:21:44 UTC
From: ricknj10@hotmail.com
Message-ID: <3d8dc0b3.94360785@news.optonline.net>
Source record: 134177

I've had this problem with my 40 m inverted Vee mounted right under a
4 ele 20 meter monobander. Extreme interaction noticed on 40 m. I
couldn't get the 40 m antenna to resonate in the band. I'll skip all
the things I went through to finally determine that the 20 m beam was
detuning the 40 m antenna (new coax, connectors, etc.)
So here's what I did :
I made the 40 m antenna into a kind-of sloper. It slopes down from
the 40 ft height on the tower to a tree at 25ft. Since I had a pulley
on the tower I was able to move the dipole a little at a time away
from the tower till the interaction was eliminated (turning the beam
changed the SWR on the dipole). The end of the dipole had to be
clear of the beam before there was no interaction.

>running down from the top of the tree.

I also had an oak hit here and there was only one "etched line" like
you described. It blew bark off all over the area around the tree but
there was no disturbance to the ground at all where the current
entered (exited ?) 2 years later the bark all around the tree
separated and the 80 ft tree died. The strike was 150 ft from my open
window and I was sure someone had just fired a shotgun at me from
directly under the window! That's why I am building a good ground
system for my tower now.

Roy, you are the cheat. Any value of resistor can be used with the same result. The process just takes longer.

Whatever the resistor value the "missing" energy is dissipated in it. Or is partially converted to sound energy. Even radiated.

Also if you want to use the radial system as a lightning ground in
addition, bare wire buried
would be the choice. As most of the energy in lightning is at 1 mhz
and below a capacitive
ground would not be very effective.

Hi,

I am trying to figure out how a 10 dB power increase (10 W --> 100W) will affect the S-Meter on the other side. I know that the S-Meter measures voltage, so I don't think the 10 dB can be applied to s-units? Any insight is appreciated.

Also, would 10 dB antenna gain have the same effect?

Thanks,

Andreas, KU7T

> How about an 80m dipole fed with 1/2WL of ladder-line? That's what I use.

You don't use a tuner, so your loss should be very slightly less than
with the coax. But being the coax loss on 80m is very low, and close to
ladder line numbers, there should be no real difference between them in
the real world. MK

> is appreciated.

The number of dB's in an "S-unit" varies all over the place depending on the particular receiver. It's supposed to be 6dB per S-unit but rarely ever is.

> Also, would 10 dB antenna gain have the same effect?

The same effect as a 10 dB increase in power? Not exactly. A 10 dB increase in power results in a 10 dB increase in all directions. A 10 dB increase in antenna gain results in an increase in one direction or maybe in a plane, but *never* in all directions. Increasing the power into a vertical monopole by a factor of ten is obviously not the same thing as putting up a beam with 10 dB gain over a vertical monopole. Which choice one makes depends on what one is trying to accomplish.

Let's simplify my question:

If I would turn the 10 dB beam into the receiver's direction, would the signal strength on the receiver be the same as with 10 dB power increase (I am not talking about S/N)? It should, right?

An S-meter is a watt-meter. It is scaled in decibels relative to 50
pico-watts.

It indicates power input to the receiver. The receiver input resistance is
50 ohms.

S9 = 50 pico-watts, which is the same power as 50 micro-volts across 50
ohms.

One S-unit = 6 decibels.

For every S-unit less than S9 the receiver power input decreases by 6 dB.

Above S9 the meter is scaled directly in decibels relative to 50 pico-watts.

The foregoing is enough for you to work things out.

The receiver has no way of knowing if a 10-dB increase comes from antenna gain or increased power to a non-directional antenna. The gain is fungible.

I'm thinking of replacing my old but reliable ground mounted Hygain 14AVQ with a Butternut HF-9V. Just curious if anyone else has made a similar switch from a trap vertical such as a 14AVQ or a Hustler BTV to an HF-9V and if there was an improvement to performance. If you had an adequate ground system for the original, were any changes required for the Butternut.

Thanks,
Jim Keller

I see a lot of people get confused about S meters. The S meter
measures the AGC voltage in
the receiver. A watt meter measures the voltage from a diode. What
matters is how it is
calibrated. Reg has a very good reply.

Any 10 DB change in the signal strength in the circuit anywhere will
cause a 10 DB change in
the S meter. If the power is increased by 10 DB or if the transmitter
antenna gain is increased
by 10 DB (in the direction of the receiver) or if the receiver antenna
gain is increased by 10 DB
(in the direction of the transmitter).

No. Your beam could have a huge null off the side and turning a "10db" gain antenna toward a receiver could result in a 30db increase. Now maybe if you aimed a dipole at a station, measured the signal strength then replaced it with your 10db gain antenna aimed in the same direction, you would see a 10db increase but at the same time see a 10db decrease in some other direction. No magic gain, just concentration of the beam in one direction.

Hi,

I want to homebrew a 5/8 wave vertical for 70 MHz

I've calculated the length of the vertical radiator to be about 2.54 mtrs,
however I do not have much idea what value of series inductance to
get a decent 50 ohm match.

Anyone suggest likely values of series L?

Not necessarily. A "10 dB beam" might well have a deep null in one or more directions. If you swing the beam so that the other guy goes from a null (-xx dBd) to the main beam (+10 dBd), then the improvement at the far end might be much greater than 10dB. On the other hand, the other guy might have started out fairly close to the main beam and the improvement might be much less than 10dB.

The difference is my 80m dipole works well on all HF bands without a
tuner simply *because* I feed it with ladder-line.

Not necessarily as it depends on take-off angle as well as gain. Let's look at it from the receive standpoint. The receiver probably cannot tell the difference between 10 dB due to a power increase and 10 dB due to additional antenna gain. But obviously it is difficult to compare a vertical monopole with a maximum gain of 0 dB at a take-off angle of 15 degrees with a beam with a maximum gain of 10dB but with a take-off angle of 45 degrees. The vertical may still beat the beam at certain distances.

That's like saying a 10 dB change in signal strength will cause a perfectly proportional change in the AGC voltage. I doubt that you can say that about most receivers. Some receivers have an S-unit equal to 2 dB. Some have an S-unit equal to 8 dB. Some receivers have a different number of dB's associated with one S-unit depending on where it is located on the S-unit meter. Roy, W7EL, has previously described a way to use an attenuator and a fixed point on a receiver S-meter to do valid measurements.

Just modeled it with EZNEC. Make XL approximately 150 ohms. EZNEC sez you
may have to increase the length to achieve 50 ohms.

The receiver input impedance is assumed to be 50 ohms, but rarely is.

>S9 = 50 pico-watts, which is the same power as 50 micro-volts across 50
>ohms.
>
Only in an obscure IARU specification, which no manufacturer follows.
S-meter calibrations vary between manufacturers, models and individual
samples of the same model.

>One S-unit = 6 decibels.
>
>For every S-unit less than S9 the receiver power input decreases by 6 dB.
>
But read the lab tests in the equipment reviews. In real receivers sold
to amateurs, an S-unit can be as little as 1-2dB at the bottom of the
scale, rising to as much as 7-8dB between S8 and S9.

>Above S9 the meter is scaled directly in decibels relative to 50 pico-watts.
>
No, it's just scaled in decibels relative to the S9 level, whatever that
may be. And the dB scale above S9 is no more accurate than the S-point
scale below.

If a station is S9 and cuts his power by 10dB, he may go down by 1-2
S-points. But if he's S5 and does the same, he'll probably go down by
3-4 S-points.

Also, the whole mess shifts up and down the meter scale, according to
whether you have a preamp or attenuator switched in, or according to
which way you're pointing your beam if you have one.

This raises another question: if *you* switch in the preamp and/or swing
your beam, has the other person's signal really become stronger? Easier
to copy, maybe... but stronger?

>The foregoing is enough for you to work things out.
>
The foregoing from Reg is enough to lure any newcomer into fantasy-land
for several years, until he gains enough experience to learn that
S-meters are not to be trusted unless you have calibrated them yourself.

5512. design for VHF 1/2 wave for bicycle?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-22 23:15:34 UTC
From: lagagnon@fakesprint.ca
Message-ID: <3d8e4dfb.3862246@news.sprint.ca>
Source record: 134202

First of all thanks to all who responded to my recent post for recommendations for a VHF antenna for a bicycle. I have decided to go with a half wave design. Larsen appears to make the antenna I want, as do some marine antenna companies, but I would prefer to build my own. Any designs out there?

I do not want a J-pole, nor anything tied to a fiberglass flag. I want it to be as slim and trim as possible and thus something with simple base and slim flexible SS whip. The design I would need would be the base transformer section and overall length of the whip to resonate at 146MHz.

Any help appreciated....Larry VE6MK.

The supposed standard is 1 S-unit equals 6dB, it rarely is in practice.

10dB is 10dB no matter what the source of the increase.

I certainly won't disagree with this point given that it has been
repeatedly proven to be the case, but I would like to know why.
Obviously a radio manufacturer doesn't calibrate the s-meter poorly just
so all the numbers fit neatly...or do they?
Or is it that there is such a wide variation in the linearity of the
gain/avc circuits in a given model receiver?
Seems to me that deciding where to put the tics on a meter face
shouldn't become so full of error.
(Staying with a given receiver model of course, not comparing Model X vs
Model Y.)
Comments?

You asked what you should do. Live up to the terms of the contract you signed!

You say that you try to use stealthy antennas. That doesn't mask the signal you are sending throughout your neighbor's homes. They have a right to live in an antenna "un-friendly" environment...That is what they signed-up for...As you did.

>cheers, CAM http://www.qsl.net/w5dxp
>
>

I think what the original poster is trying to figure out is what an S
meter really reads.
What he is trying to get at is if the S meter reads voltage then he
is thinking that it should take
20 DB signal change to see 10 DB change in the S meter.

While it is very true that the calibration of most S meters on most
receivers leave something to
be desired, it is really power level differences that the meter is
loosely calibrated in.

In reading the following sentences of my previous post I am saying
that it does not matter where
the 10 db comes from. Transmitter antenna gain, transmitter power or
receiver antenna gain.
They all will give the same increase in S meter reading. If the meter
happens to be calibrated
right then it will show 10 DB change.

"Any 10 DB change in the signal strength in the circuit anywhere will
cause a 10 DB change in
the S meter. If the power is increased by 10 DB or if the transmitter
antenna gain is increased
by 10 DB (in the direction of the receiver) or if the receiver antenna
gain is increased by 10 DB
(in the direction of the transmitter)."

Nothing complicated. Not attesting to how accurate an S meter is or
isn't.
Of course using a calibrated attenuater ahead of the receiver and
setting the signal level to the
same point on the S meter takes the error out of the S meter circuit
when making actual
measurements.

It's not precisely what you are asking for, but a vertical, center-fed 1/2-wave
dipole would eliminate the need for the ground plane which an auto provides, but
you're not going to get on a bicycle. I'll leave the construction details to
your imagination...

True! the deflection change may be anything in indicated "S" units but
if caused by a 10-db change in received signal, the change in deflection
represents 10 db. Marks can be made on the meter face or glass to
provide calibration for these two known levels and the indication of
their difference is repeatable.

Following me there is no difference. It's better to have 100+ radials of normal copper wire (> quarter wavelength). Ground rods will help for lightning if placed close to the antenna pole, with a protection hardware. I have used a grounded pole supplied with a gamma match.

Dave wrote;
"with a ground mounted vertical using bare copper wires for radials will it help, hinder, or make no difference to put 8 ft ground rods at the far ends of the radials?"

Probably no difference.

Assuming you are using the vertical for h-f, the classic ground system studies were conducted at 3 MHz, Ed Laport has a report. It is found on page 118 of "Radio Antenna Engineering":

"The ground system performs solely as a circuital element with the shorter vertical radiators, serving to reduce ground losses. With a system of 120 radial wires buried near the surface of the soil to a length of 0.4 to 0.5 wavelength, almost all of the ground current is collected from the electric field above the ground system and current densities below the ground system are very small."

The conclusion is that the radials are so long that displacement current levels at the ends are insignificant so it makes no sense to use ground rods out there. Also the multitude of radials has collected displacement current from the tower so effectively at shorter radial distances that ground currents deeper than the radials is inconsequential. So, ground rods aren`t worth the effort. They are not usual in AM broadcast transmitting systems, but may be found in low frequency systems where skin depths are large and radials tend to be short in terms of wavelength.

Best regards, Richard Harrison, KB5WZI

I think transverters are used for increasing the working frequency not decreasing it, i.e. passing from HF to VHF. I never saw plans for passing from 10m to 20m or even 80m. The contrary would be easier as 10m is an harmonic of 20m or 80m.

All

With wire antennas when is it appropriate and necessary to use a balun.. I understand that basically its an impedance matching transformer. Does it also isolate RF and keep it off the feed line and out of the shack.. Oh i'm using a G5RV full size and a differential T turner from MFJ..

Are there some good links on this subject?

Many thanks

Rich KG5IF

At least in England, there has been kits for allowing 2 m multimodes
(such as FT-290) access to the HF bands using a transverter.

>The contrary would be easier as 10m is an
>harmonic of 20m or 80m.

This is just a situation you try to avoid.

For instance a transmitting converter from 28 Mhz to 144 MHz often
suffers from these harmonics. Assume you want to transmit on 145.100
MHz on a repeater input and you set the HF radio to 29.100 MHz. The
5th harmonic of that is 145.500 Mhz, which falls in the middle of the
FM calling channel :-).

Thus, you have to be very careful to filter out any 5th harmonic from
the HF signal and also take care that the mixer does not generate any
larger amounts of 5th harmonics of the input frequency.

In general you should design the frequencies in such a way that no
harmonics from the low frequency signal or the local oscillator signal
fall close to the desired output frequency band, since it would be
very hard to filter them out, once they have been created.

>Or is it that there is such a wide variation in the linearity of the
>gain/avc circuits in a given model receiver?

Yup. The gain/bias characteristics of dual-gate MOSFETs and PIN
attenuators are not guaranteed to be accurately "log-linear". AFAIK,
only the Analog Devices AD600 amplifiers (as used in the Carver IF strip
for example) will guarantee an accurate S-meter response... and those
are much more expensive than the penny components that manufacturers
like to use.

>Seems to me that deciding where to put the tics on a meter face
>shouldn't become so full of error.

That's true for analog meters, but bar-graph digital meters are much
more restricted. On the other hand, there's no reason why a digital
S-meter shouldn't be linearized in software. Some professional receivers
are beginning to do this, and also to take account of preamp/attenuator
selections and the change of sensitivity with frequency. Only then do
you get a real measure of the available power or voltage at the input
terminals.

But with an amateur S-meter, the only two things you can reliably say
are "You got stronger" or "You got weaker".

Toko have these for I.F.'s of 6m or 2m. The difficulty of using 10m
I.F. is that of keeping mixing products out of the TX output. For
Example take IF of 28.000Mhz mixed with 31.5Mhz to give 3.5Mhz
(difference) and 59.5Mhz (sum). The Eighth harmonic of 3.5 is ?? what
?. Now work out other combinations for the n* sum +/- n*diff) etc etc.
And then do the same for all the other HF bands. Not a pretty sight.
The 2m I.F. version would be a lot easier to keep clean.

Hi,

You are right...

I was in contact with the designer of my RTX, Toshii Torii, JA6QXW which
website in linked to mine.
He told that when the antenna tuner is tuning about 10W comes to the antenna
terminal and this to the mag.loop interface.
But up to now I have always thought that antenna tunesr work with a fictive
charge and do not emit on the air.

The 10W of power when tuning explains also why a small stabilized power
supply of 13.8V/ 3A used in place of a more powerfull i.e 20 A shuts down a
fraction of second the RTX when tuning.

At last with the loop, when I swich off the AT tuner I receive much better
all AM broadcasts below 3 MHz (i.e signal 58 in place of 51).
With my new tests I observe that even without AT tuner (button AT tune off)
all HF bands are matched to my 50 ohm (but it is maybe normal as I tuned a
first time) and perform better than my long wire on all band from 20 m and
above (up to 10m) with much less QRM.
Between 40-160m, the loop attenuate a lot signals but remove QRM.
NB. the magnetic loop ALA-330 is always a bit sensitive to QRM generate by
my nearby computer or recharger. the level of QRM is hover more that 4 times
attenuated (1 to 3 points)
See details on my website.

We learn from our mistakes... !

Source record: 134228

Although some may disagree (I can hear the howls of protest already), but it is good engineering practice to use some form of feedline choke anytime an unbalanced coaxial line is used to feed a balanced element such as a dipole. This could be implemented in the form of a 1:1 balun installed at the feed point. It could also be implemented in the form of a current choke made with ferrite material -- or by simply looping a few turns of coax at the feedpoint (see the ARRL Handbook for specific applications) . The idea is to prevent the outer surface of the coax braid from becoming a third uncontrolled leg of the antenna--with the potential for introducing several problems including RF in the shack, unwanted noise pick-up, detuning of the dipole to a displaced frequency, and even--in some cases--significant alteration of the antenna pattern. In the case of the G5RV, the "choke" is normally installed at the junction between the balanced and unbalanced feed line rather than at the antenna's feed point.

Completely right. My post was only general.

And I didn't know there was rigs transverting VHF to HF. I thought it was too hard in terms of filtering. Sorry for making confusion.

Source record: 134232

What effect does a metallic center support have on a multiband dipole patterns? Specifically, a 160-meter dipole is very long and requires some kind of center support when fed by ladder line or larger-diameter coaxial cables. How does this effect the pattern on each of the 160-meter through 10-meter amateur bands? Does the height of the support make a difference?

>for...As you did.

Silly boy....show me ANY contract that states that you cannot generate RF. The man is trying to comply with the limitations...he's not trying to stick a 100' tower in his back yard. "Mask the signal you are sending throughout your neighbor's (sic) homes"....hey, wake up, boy! Everytime your neighbor turns on a cell phone or cordless phone, the same thing happens! How about your bloody FRS radios? Woops, there goes one of those nasty RF signals! And, oh, my god, here come TV signals!!!!! AAARRRRGGGHHH!! (waving copy of CC&R's at radio waves)

Unless it is expressedly written that NO AMATEUR RADIO operation is allowed in the neighborhood (and that most likely would be unenforceable...any lawyers want to weigh in on this? I know the "no transmitters" clause is unenforceable), he can put a potted plant vertical out on his patio (assuming a back yard patio), or a dipole in the attic, or a vertical in his chimney, or a Force 12 Flagpole antenna up (tho some anal areas do regulate flagpoles...check the accursed CC&R's) and no one can do a bloody thing. Why? 'Cuz he lives in the States, and there are a few rights not yet infringed upon still in existance.

Heck , Randy, what do you want? I've read a lot of your posts...you're intelligent, even witty on occasion. What is the problem with finding a solution to a vexing problem (esp. one where he moved into the area and THEN gets involved in amateur radio? Note that he said he'd been there 18 YEARS, and only recently had gotten his ticket). This must be your personal chain to pull. Guess everyone has to have one. As for the original poster, go to town. String antennas in the attic, get a carpenter to mod some trusses in the attic

to allow enough space to turn a beam (friend has a tribander in his attic....big house, tho) and load the stovepipe they use in new fireplaces with a tuner! Enjoy!

Andrew
"...if one tolerates bad manners, they grow worse. I must find the oaf who did this thing, explain to him his offense, give him a chance to apologise, then kill him." (R.A. Heinlein, "The Cat Who Walks Through Walls")

5548. Re: How much does a metallic center support effect multiband dipole patterns?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-23 13:21:49 UTC
From: John Passaneau <jxp16@psu.edu>
Message-ID: <amn4gp$13r8@r02n01.cac.psu.edu>
Source record: 134239

Hi Bill:

If the antenna is symmetrical about the metal support it will have no detectable effect on the dipole at all.
There is a region of almost zero field in the center of a dipole and if the dipole support is in that area, very little current will be induced into the support and it will have very little effect on a dipole. I modeled a 160m dipole, 160' up a 180' tower for a friend and this was one of the questions he asked. This was a very large diameter tower, larger than 10' across at the bottom. So with the power set to 1500 watts, the model showed less than 1microamp of current flowing in the tower, grounded or not. So metal supports are not a problem with dipoles. Remember if you use open line to keep it a minimum of several wire spacing away from metal and more is better. By the way the dipole I modeled came out within 6' of the length I predicted and the Z and SWR bandwidth were also as predicted.

Hope this helps..

"Speciffically, a 160-meter dipole is very long and requires some kind of center support when fed by ladder line or larger-diameter coaxial cables."

To work DX best, this antenna must be as high (1/2-wave) as it is long. For many hams, a good ground system and a vertical, an inverted-L, a Tee, or some other antenna with substantial vertical polarization are better bargains.

A metal supporting tower will be energized by vertically polarized energy in the vicinity. Borrow a copy of John Devoldere, ON4UN`s "Low-Band DXing", and study it, especially chapters 9 and 10, for your questions. These questions may require elaborate answers.

Best regards, Richard Harrison, KB5WZI

Just comment here Larry... are you sure a steel whip would be safe on a mountain bike? The potential for injury would be quite high should you fall on it (or poke an eye out).

Given a choice I would "remote mount" one of those "extra long" rubber ducks on a far corner of the luggage rack on the back of the bike. I've seen plenty of 2M 1/4 wave units, I have no doubt some manufacturer must make a 1/2 wave version.

Result would be similar, but I assume it would be a little safer.

I have had the VA-1 for a couple of years. The MFJ covers a wider frequency range, as it includes vhf.
The Autek VA-1 fits in my shirt pocket, and provides more information than the MFJ. If the added information is not of interest to you, the cheaper version of the acute is also fairly useful.

Don; It all depends on what you want from the analyser. You can download the MFJ manual and read it through. The last time I looked (some time back), MFJ made it perfectly clear that their unit cannot differentiate between capacitive or inductive reactance. Based on this fact alone I selected the Autek which can and have had great success. Read their manual, you'll be amazed what it can do that the MFJ can't. Not as pretty and you can't use the counter separately but it's cheaper and does alot more very accurately. Good luck, Keith, VE3JKC.

About 0.37 mh for an ungrounded coil, and about 0.69 mh for a grounded
base coil. I'd make the radiator 2.55 mtrs. "100.62 inches" But 2.54
would work. MK

Roger that, Allen!
>
> Given a choice I would "remote mount" one of those "extra long" rubber
> ducks ....

And that too, except maybe put the duck on a 1/4 wave sleeve to create a vertical dipole (Bicycle's a lousy ground plane). Also recommend stick with a 1/4 wave if you plan on talking while in motion. A half or 5/8 wave vertical achieves gain by flattening the field out toward the horizon - an excellent trade-off *IF* the vertical stays vertical - like on a house or car. Unfortunately, it does not on a bike or motorcycle so your transmit and receive signals fade as you lean the antenna's beam into the clouds then dirt (No need to ask how I know that ;o).

I was not a clear as I could have been. What I meant was that conductive objects that are in the plane of symmetry that bisects a balanced antenna, like a dipole, any current induced into that conductor by a field from one side of the dipole, will be canceled by a current induced into that conductor by the field of the opposite polarity from the other half of the dipole. Remember that the polarity of the currents in each half of a dipole are always opposite. This why there is the recommendation that feedlines comes off a dipole at right angles to the dipole for as long as possible. Dipoles are usually hung symmetrically from their center support, so there is little induced current in the masts. Of course the more un-symmetrical the dipole is, the greater the induced current.

Baluns are for mating balanced devices to unbalanced devices. They can be made either 1 to 1 or they can be made to not only act as a balanced to unbalanced but at the same time to change the impedance to another vlue. If you don't need to change the impedance then the baluns are mostly to make more mney for the seller.

Many times a few turns of coax will do as much to keep the RF off the feedline as a balun/

Has anyone here used the Diamond HF50CX antenna? I was thinking of
buying one and was wondering about the performance. I am sure it would
be a step up from the 1/4 wave I am currently using.

I think it would be a waste of rods for the most part. Wouldn't be too much different than just adding an extra 8 ft to the radials, which would also be a waste of time, I think. Most of the currents are at the base of the antenna. Thats where you want the most metal. I would think at the ends of the radials, the current has dwindled down to a point where the rods would be fairly useless. I'd stick the rods at the base, to make a better lightning return. As far as radials themselves for rf purposes, I don't think ANY rods are needed, as long as you have enough radials spread out. But they are a good idea if you take lightning strikes. Rods are semi useless as an rf return. Radials are much better per pound of metal, rf wise. Or thats my view anyway... MK

Dunno...When I make halfwaves, I use a single turn loop that is tapped for best match. A cap can get a closer match if needed. But this may be sort of bulky on a bike. The coil wouldn't have to be too big though for 2m use. I use about 9-10 inches on 10m, so I'm guessing a 2-3 inch coil would be about right for 2m. Normally about 50 pf is needed as a cap on 10m, so I would try about 10 pf for 2m use. These can be made from a short length of coax. Check the cushcraft web page for a PDF file "manual" on the 2m ringo. This is what you would be making. Heck, you could probably buy or make one of those, and then use the thin whip instead of the tubing they normally use. I'm not sure what mobile 1/2 wave antennas are available. All I hear about are mainly the "stick on the window" type with capacitive coupling to the feedline. About 38.5 inches tall would be about right for 145 mhz. MK

Dick,

My case may be a little more exagerated of a hillside location. I
can drive up a cross street and view my antenna from the side of the
hill. A little guesstimation with a protractor shows me that at a
takeoff angle of 20-30 degrees most of my signal goes into the side of
the hill. At times I do receive the East Coast but I attribute that to a
multiple hop condition where the takeoff/arrival angle is much steeper.

Not really what I would call appalling. Amateur radio operators are technically savy and not merely appliance operators... Right???

As such, they realize that S-Meters are nothing more than a sampling of a signal in a stage of the receiver, rectified, and displayed visually on a meter, led, etc etc. They also know that the meter only offers minimal information on relative signal strength (Joe's signal is slightly higher on the S Meter than Fred's).

But then again, I have heard 2 Meter operators on repeaters saying that someone is "S-9" on their meter, "same as Fred, but for some reason he is noisy." Now that scares me that someone could get a license without knowing that the S Meter reflected the strength of the repeater signal into their receiver and had nothing to do with the transmitting station's signal whatsoever. Bet if they had a rotatable beam, they would try pointing to the transmitting stations QTH :-)

Yep and depending on the configuration, it isn't even constant with
varying signal level. Many years ago, I calibrated the input
impedance of a Collins 51S-1 receiver as a function of agc voltage.
We were using it to measure some parameters on an air-to-air missile
and needed to account for the mismatch loss. I don't recall the
numbers, but there was quite a variation.

|
|>S9 = 50 pico-watts, which is the same power as 50 micro-volts across 50

Unless it's 100 uV = S9 or whatever else the manufacturer says it is.

"S" meters should be labeled "relative signal strength", with no
values whatsoever.

But they (rods) are a good idea if you take lightning
> strikes.

==========

If radials are increased in length by the depth of the rods why are rods a better idea at the end of radials if you take lightning strikes ?

The radials burn out anyway. If you are worried about burning-out radials then make the radials as thick as rods !

The antenna radial system should be arranged with only the radiating system in mind.

The lightning protection system should be considered as a separate matter.

The two cannot destructively interfere with each other. They can only provide mutual enhancement.

To protect the tuner make the roller-inductor from 1" diameter, silver-plated copper pipe.

In the UK I have never seen lightning actually strike anything although once in a while I have heard thunder.

But last night I was at the epicenter of the strongest earthquake in the UK for 20 years. I distinctly observed the level of the port wine in my glass wobble just as I was about to take a sip. Very frightening ! Did it make the international newspapers ?

The BBC sent out a warning that it occured 7 miles right underneath my house and follow-ups could be expected. So tonght I've re-inserted the cork in the bottle.

Hic !

Why not try a 3/8-wave with a series capacitor.

The trick is to vary antenna height until the feedpoint resistance is 50 ohms (or 75 ohms depending on what the coax Zo is) and then tune out the residual reactance with L or C. The end result may not be an exact height of 3/8ths or 5/8ths wvelenghts. But that is immaterial.

From: KD4ADV <nohooch@nospam.com>
Message-ID: <WtOj9.19509$u7.964100@news.direcpc.com>
Source record: 134268

I have this concept and innovative mounting scheme that might work for single antenna users.

Going on vacation, camping or live in a condo or those subdivisions that frown on antennas on someone's back yard?

Go to Lowe's and to the paint section.
Look for these handles that are yellow with the "DANGER" stickers on them.
They have a button so you can extend the inside section to the length you want.(locks into place)
The section goes all the way out without coming completely out the handle!

They have sizes ranging from small to medium to long!

There is a part on top that would need to be sawed off with a pipe saw. (for the roller attachment)

After that, you can mount -for example, an MFJ 5/8 - 2meter groundplane antenna.
And check the SWRs.

A ground base can be constructed to put the bottom end into to keep the pole upright.
OR, better yet- mount it on a building near or on the rooftop for the groundplanes to have room!

Ideal for a scanner antenna, too ;)

If you mount it on the side you might need a stand-off that will support it.
It's not Heavy.

I haven't the money at this time to buy one.
I just had that idea come into mind while cleaning out the garage.

If anyone has ever tried similar attempts,
please reply and let me know before I waste money. ;)
It just sounds like a good idea!
Of course, gotta watch out for the RF coming off the antenna.
I will be running low power at least from my mobile.

There was a long pole that got sort of wobbly when gravity started taking over.
But, that's where guy-wires would come into play!

--- REMEMBER ---
This is for single antennas ONLY!
Either Vertical or a small directional -commercial or homebrew.

(Not for the antennas that belong on the towers with 5 or more Elements!!)

73s,
Tnx in advance :)

Ground rods on radials can dissipate more lightning energy than just
radials. There is more earth
around a ground rod than there is around a radial. The earth in the
vicinity of the radial or rod
can only get rid of so much energy as the soil becomes saturated
around it. Thus the reason for
multiple ground rods spaced apart from one another and tied together
with radials in a good
lightning ground system. However placing ground rods at the ends of
long radials will probably
do little as the inductance of the radial will be too high for most of
the lightning to see the ground
rod fully. It would be much better to place the ground rods closer to
the antenna along the
radials. Rule of thumb is to place ground rods apart by the sum of
their lengths.

A good lightning ground system usually makes a good RF ground system
too.

Five reviews - several short-term owners, one from somebody who says he's been using it for more than five years. People seem to be pretty happy with the antenna, not so happy with the manufacturer's responsiveness. Haven't used one myself.

Another option, vaguely similar, might be the Traffie Hexbeam (http://www.eham.net/reviews/review/9579). The Hexbeam is physically larger, I believe, and is rather directional, where the CobWebb is largely omnidirectional.

From: rsparks <rsparks@elltel.net>
Message-ID: <3d8fd286_2@corp.newsgroups.com>
Source record: 134074

When the two sides of your dipole begin behaving like two L antennas set back to back, and the resulting pattern is not what you want, then it is time to use a balun.

You will get the "two L" pattern if both sides of the dipole do not have identical electrical characteristics. This will happen if one side is closer to trees, ground, other antennas, feed line, or any conductor, than the other side is. Many people also feel that the braid of a coax feed line unbalances a dipole so much that a balun should be used.

The balun will act like a RF transformer transferring the impedance of one side of the L to the other side, making both L antennas equal in impedance. The feed line "sees" none of this, but sees only that it is feeding two L antennas 180 degrees out of phase. The vertical portions of the L's are transmission line, the out of phase currents cancel all radiation. The horizontal portion of the L's make a dipole with equal currents (thanks to the balun) so the antenna feed impedance is the impedance of the dipole, and the pattern will be the pattern of a dipole.

Can you still have common mode currents on the transmission line when using a balun? Yes, they
are unavoidable but can be minimized. This occurs because the unbalanced dipole is not fed at the electrical center of the antenna. As a result, the sum of the voltages on the two feed point sides (when measured to ground) will not be zero. If
the sum of the two voltages (measured to ground at the feed point) is not zero, a common mode current will be forced onto the transmission line.

The addition of a balun will change the tuning of the common mode system, but can not 'block' the current like a switch. Instead it will move the high current point to a new location which can be predicted by considering where the current would be moved in each of the two L's with the addition of the intrinsic impedance of the balun to each side.

I know that the description I just offered is not the same as the description found in the ARRL Antenna Handbook. Never-the-less it works for me, it should work for you.

Would 10 or 12 gauge insulated stranded copper wire be as
good as 20 gauge.

Source record: 134077

Funny that you should ask. After using Cushcraft verticals for the past 10 years, I decided to put up a "crazy loop". Construction details: approximately 300 feet of 16 gauge speaker wire (unzipped into single strand) purchased at home depot and fed with 450 Ohm window line (about 50 feet). The shape is a very distorted triangle: Feed point is eave of house (about 22' up), fans out to palm trees (both @ about 30') that are about 40 feet apart and 50 feet away. Then both converge at a 45 foot high tree on a 25' hill about 100' back and not really at the midpoint between the palms in the other axis.

I listed all the details to point out that anything goes as long as you have a decent antenna tuner. My MFJ-989C can tune the loop from 160 to 6 meters with no problem. In every case since I put it up a few days ago, the loop is as loud or louder than my R-8 vertical. On 160 and 80, using the vertical isn't even an option. I had one station in Minnesota ask me how many hundreds of kW I was using on 12M. I didn't think it was such a big deal until I switched to the vertical - she said I was about a 57! I've gotten similar comparison reports from South Korea, Kenya, Indiana, etc. In fairness to the vertical, I'm feeding it with about 150' of 9913 coax, so there's a few dB lost there.

Anyway, hope my experience is of some use. Give it a try, you never know what will happen, and best of all - IT'S CHEAP!

5587. Proper/ideal choice of T-tuner settings

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-24 05:17:14 UTC
From: Will White <googlyelmo@earthlink.net>
Message-ID: <3D8FF578.BF1DF082@earthlink.net>
Source record: 134078

I find that I can get virtually the same match (especially on 30 and 10 meters) between my rig and LL fed 67' inverted V, at *more* than two settings with a T-tuner . My question is this: granted that in choosing between hi-L/low-C and hi-C/low-L, the latter is preferable for efficiency's sake, but given the *same* amount of L, if one cap is set near max, and the other set near minimum, which should input and which output?

5588. Correct ratio for design of loading coil

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-24 05:29:04 UTC
From: Will White <googlyelmo@earthlink.net>
Message-ID: <3D8FF83F.251811B7@earthlink.net>
Source record: 134079

I understand that the textbook correct length to diameter ratio for a loading coil is 2:1. Can't some gain in Q/efficiency be realized by making a coil much wider than it is long, say reversing the above so that it is 1:2, length to diameter?

As you have observed, there is (in theory) an infinite number of
combinations of three variables that can effect a match; only one of
which offers the best efficiency. This assumes that the variables are
variable enough.

However, once you've fixed one of them (the L in your example), there
is one unique setting of each of the other two (the capacitors) that
will give you a match.

It is always appropriate, if the transmission line is coax. Is it
absolutely necessary, no... but it is still good practice to use one.

|> transformer.

It may or may not be an impedance transformer, but its primary
function is to present a high impedance to common-mode current on the
transmission line.

5592. VHF and UHF yagi spacing

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-24 10:07:38 UTC
From: rbarrios@gmx.net
Message-ID: <ab7385fd.0209240207.1e0399ea@posting.google.com>
Source record: 134083

Hi all again,

I'm going to install a pair of yagis:
- VHF TONNA 20809 (1.65wl=3.47m) (www.f9ft.com)
- UHF TONNA 20919 (4.02wl=2.82m) (www.f9ft.com)

I will use vertical polarization and I wonder what spacing between them should I use. I plan to use a diplexer on top of the mast to feed both antennas with a single feedline (unless someone gives me a reason not to do it...).

As far as I know, the interaction between both antennas won't be as dramatical as it would be if they were feed with the same signal (the diplexer should work as a pretty big isolation), but sure they won't work if I put them too close.

How close is too close ???

Thank you very much

EB4EQA, Roberto

10 AWG is larger than 12 AWG which is substantially larger than 20 AWG.

An insulated wire radial is completing a displacement current path with an antenna. So, it is a capacitor plate, the other being the antenna. Capacitance depends on plate size.

If capacitance between an antenna and its radials is too small, the antenna displacement current will connect with other conductors (often the earth) which make a lossier connection with the radio.

The displacement current loss in the radial depends on its resistance which is higher in a smaller wire.

Larger wire makes more efficient radials.

Best regards, Richard Harrison, KB5WZI

Source record: 134084

#16-#20 AWG size copper is fine IF, (and only IF) 30-60 radials are
being installed. Small wire size is immaterial when a large number are
used.
If only 4-8 radials are considered (at a great return loss) then
larger #12 should be used.

Comtek Systems recommends 60 radials for each of the 4 verticals in a
4-Square phased array, with a minimum wire size of #16.
www.comteksystems.com

Good luck,
Jim, K4SQR

>How close is too close ???

There is information on my web site, based on 'capture area'.

Minimum stacking distance would be one-half of Tonna's recommended stacking distance for two 20919 yagis. This is 0.5*1.25m = 0.6m approximately. For vertical polarization, that should be the closest distance between the ends of the elements.

That arrangement will place the 2m yagi outside of the capture area of the 70cm yagi, so the 70cm yagi should be OK.

The 70cm yagi will still be *inside* the capture area of the 2m yagi, but the interaction should be small.

Rich, KC5IF wrote:
"With wire antennas when is it appropriate and necessary to use a balun."

When you want the directivity predictable for a dipole, or when too much r-f returns to the shack via the coax, a balun may be your friend.

Plenty of very satisfactory dipoles have been directly fed from coax with no balun. I`ve put them up myself around the world commercially. The r-f on the coax may have been beneficial in vertically polarized radiation reaching contact points the dipole itself wouldn`t reach. A good ground on the radio helps vertical radiation and helps reduce r-f in the shack.

I did not get mine at Lowes, but rather at the other HomeMegaImprovmentDepot
store.

> They have sizes ranging from small to medium to long!

I am using the gray one that has 3 sections that extend to 23 feet. IIRC it
was about 30$

>
> There is a part on top that would need to be sawed off with a pipe saw. (for
> the roller attachment)

Don't cut it off. Instead, get one of the small 3 piece wooden extensions
that come with the plastic couplers to connect them together. Use one
coupler and 1 section of the wooden extension on top. This way you can still
use the extension pole for painting.

>
> A ground base can be constructed to put the bottom end into to keep the pole
> upright.

While at the store, get a 2 inch pipe flange, a short length of threaded
iron pipe and a few nuts and bolts. Mount the pipe flange to the center of a
2x2 ft plywood square and thread in the pipe. Youy can just slip the
extension rod into the pipe and it is rather steady. I also drilled some
small holes about 2 inches in from each corner of the board, and use long
gutter spikes to nail it into the ground. It is extremely solid that way.

>
> Ideal for a scanner antenna, too ;)
>

Funny you should mention that. I also use the cheap 20$ RS scanner antenna
mounted on top of the extension pole. It works great as a 1/4 wave 2m
groundplane, it also works well on 440.

> If anyone has ever tried similar attempts,
> please reply and let me know before I waste money. ;)
> It just sounds like a good idea!

it is a good idea, and works fairly well, in fact I had the same one myself.

Actually, up-conversion has the advantage of fewer potential for birdies
from harmonics of the oscillators. Most of the better transceivers use
an IF higher than the Fo.

I have no experience with the 10m radio you mentioned, but it sounds
like your project has potential. Additional circuitry could be built into a
housing extension, replacing the bottom cover? The down side, It
could cost more than buying a used HF multi-band rig, but that idea
never scared any hot rodders from building. Sounds like a neat
project.

> W2WO

Bill,

I have not seen that particular antenna in the literature I have, but have seen a 2 wire wideband 75 meter design in either the W1FB antenna notebook or the ARRL antenna handbook. This consisted of two slopers 55 feet long fanned from a common point to about 8 - 10 feet of seperation at the low ends. The SWR was suppossed to be flat for most of the band. I built this some years ago and hung it at about 35 feet on my tower which has a very large tribander and VHF antenna at the top. The best SWR I could get was about 3/1 and it was flat at that point for about 250 khz. Although I use half slopers extensively on 160, 75, 40 and 30 meters, I have always had problems getting better than a 3-4/1 SWR on 75. The antennas always perform well even if a tuner is needed on 75.

Thank you for the note. I guess a large metal mass is needed above the half-sloper ----- my 2 element quad is probably not large enough. (And my 40' tower is not very high.) They sound like great antennas for the low bands, provided the user has an appropriate tower/antenna combination to start with. From the few writeups available, they sound better than a shunt-fed tower because the power curve starts from the top (or near the top) of the tower rather than at the bottom of the tower.

Thanks for the note,

Bill
W2WO

It's wide band, alright, as long as you don't mind the impedance changes and the matching network you'll need to use it :-)

I really doubt this article can do what they claim. There is nothing special about a vertical folded dipole, off-center fed. But I have to wonder if the antenna pattern diagrams are accurate.

It works well in practice.
The polar diagrams are entirely logical.
Test diagrams have been produced at Christchurch University, New Zealand.

The pertinent question may be; whether you have any instant reason to
dispute them, other than natural flare.

> . . .
> So what do you think?

As I said before, there's a great deal of interaction among the fields from the currents on the sides of the disk and with the wires. This is why your experiment failed.

Not only do the fields from the currents interact with the wires, but the currents on the two sides of the disk interact with each other. The field from the current on one side of the disk doesn't just abruptly end at the edge of the disk -- it fringes around the disk. This induces a current in the other side of the disk. And that induced current's field fringes around and modifies the original current. These modify the conducted currents that you're concentrating on.

Until you include in your explanations the total interaction that's going on, any conclusion you reach, whether it happens to be the correct one or not, is bogus. You're wasting your time coming up with explanations for why the conducted currents behave as they do or as you presume they do, while simply ignoring the very significant and complex interaction that's going on. And, rest assured, that if you do find a way to include all the interactions (it won't be easy, if it's possible at all without a good and very expensive field modeling program), it'll have to include skin effect in order to explain what you've observed.

>. . .

This is an unfortunate myth that some old wives and Gurus -- even
iconoclastic ones -- keep perpetuating.

The fact is that the S meter is nothing more than a voltmeter connected
to the receiver's AGC line. The AGC voltage is approximately logarithmic
with respect to the incoming signal level, so the S-meter indicates the
incoming signal level in a more-or-less logarithmic fashion. On almost
no commercial amateur receiver meter is an S unit equal to 6 dB. It can
be anywhere from less than 2 to 5 or more, and can vary a great deal
over the dial. On my Icom 730, for example, preamp out, 7 MHz band, one
S unit varies from 1.3 dB near the bottom of the scale to 4.0 near the
top. The "10 dB" over nine increments are 5.6 to 13.5 dB. Switching from
a dipole to a rather poor 3 element beam would move my receiver's S
meter from S2 to S5 (S2 to S5 is 5.2 dB). If I believed that my S meter
was 6 dB per unit, I'd conclude that the beam's gain was 18 dB better
than the dipole. And that amount of gain would require a boom length of
about 25 wavelengths, or about a quarter mile on 20 meters. Mistaking
the gain of a 3 element beam for one with a quarter mile boom is the
kind of mistake you can make if you simply assume that your S meter is 6
dB per unit.

Until the fairly recent availability of some good Analog Devices chips, it's been very difficult to make a circuit that has a truly logarithmic response over a wide range -- especially if the temperature can vary. There's no reason for an AGC circuit to have this level of precision. The S meter is really just a convenience, but many naive hams ascribe to it a quantitative measurement capability that it simply doesn't have, nor was it intended to have. It's not the S-meter's fault that the units aren't any particular number of dB and that they're not the same everywhere on the scale. It's solely a faulty assumption by hams that it is. No amateur receiver manufacturer that I'm aware of makes any claim at all about the quantitative value of the S meter readings except. It's like assuming that each turn of a water faucet handle will increase the water flow by some fixed amount, then complaining that the faucet manufacturers don't calibrate them.

The fact is that it would be quite costly for receiver manufacturers to include a truly calibrated and linear signal strength meter. Most amateurs simply wouldn't pay for it, so it would be foolish for the

manufacturers to bother. And, ironically, if you put a 6 dB per unit S meter on a ham receiver, you'd undoubtedly get a bagful of complaints about how "dead" the S meter is.

I noticed a manufacturer or two selling a "Ground Coupling Base" for a vertical antenna. The idea expressed as a large sheet of metal acting as a capacitor plate to Mother Earth.

Is it true that a large number of radials is closer to the plate area than a small number of them? Maybe what we should be going for in a ground plane or radial field is total area not length? What is the resonant frequency of a square or a ractangle?

Is this something like a Windom? There is a feedpoint position on a
Windom-type antenna where the ratio of voltage to current is somewhat
stable for harmonically related bands. Perhaps this is the vertical
version of the clothesline antenna, a Windom-like version of the folded
dipole?

Rick,

Have you done anything with geometric shapes? i.e. squares,
rectangles or circles? Several manufacturers are marketing portable
vertical antennas with a mount that is a square(MFJ) or rectangles(Alpha
Delta). They work as a capacitor plate. Perhaps this might make an
efficient way of coupling to ground if it were know what the resonant
area for a given frequency or range was? I'm wondering if a particular
area would result in a higher current in the ground path. Maybe the
"Ideal" radial field below a vertical antenna is not a radial field at
all but a galvanized steel plate? There certainly is some anecdotal
evidence with hams I've contacted with a vertical atop a trailer or
aluminum building. They're almost always stronger than you'd expect
(Admittedly unscientific). Also sheet metal is cheap.

Hi Peter--

Chicken wire works great--I know a chicken farmer in Maine who got a killer signal by burying all his old chicken wire and tin roofing in the back yard with his bucket loader. Metal plates aren't especially useful unless they're v-e-r-y large. Tinfoil is a good idea. Take up all of the sod from your lawn, cover the entire surface with strips of foil, then put the sod back down again. Now THAT will improve your ground conductivity!

> Would 10 or 12 gauge insulated stranded copper wire be as
> good as 20 gauge.

==========

For buried radials tt depends on number of radials, on radial length, on operating frequency, on soil conductivity, on soil permittivity and on what you mean by "good". But these are theoretical considerations.

As a very crude but quite sufficient guide, the loss resistance of a radial system of 10 gauge wires is about 75 percent or more of the loss resistance of a 20 gauge system. (Sorry Roy I have no measurements to support this factual statement).

It is sufficient because hardly anybody knows what the soil loss resistance in THEIR back yard actually is. This in itself makes discussion hardly worth while. It's a fruitless passtime. Punching numbers into computer programs purporting to give answers with an accuracy of centi-bels but calling for soil resistivity is meaningless for the same reason.

Returning to the subject matter - In ordinary soils switching from one wire gauge to the other will make no observable difference when in the midst of many more uncertainties. The amount of installation labour is the same for both. Dig in whatever you have available. If buying new then you may choose the less expensive. (Good or bad ?) I just keep a stock of enameled 20-gauge all-purpose bell wire.

If you hope to have a long-lived installation then choose the thicker wire. Stranded stuff will corrode more rapidly than solid wire. But if you already have stranded wire doing nothing then by all means use it. In general, amateur installations are short lived. After a few weeks or months amateurs are eager to try something else. My own time span is about 10 minutes. Durability is of little consequence. Alligator clips are the vogue for antennas and radials.

Stranded wire makes no electrical difference. Neither does ordinary thin insulation.

For elevated radials use whatever is available and economical for you. Only its weight, tensile strength and cost need be considered.

Source record: 134118

Dear Roy,

We've been through all this before.

The S-meter is a power (watt) meter.

As I've previously suggested to you and you have yourself described how to do it. Calibrate your meter according to the generally accepted de-facto standard. All your worries will then fade into the sunset.

You have a signal generator and an attenuator. Replace the existing meter scale with a blank and use a fine pen with black ink.

May I repeat - at HF, the common or garden S-meter is primarily intended to indicate dB relative to 50 pico-watts power collected by the antenna. The antenna tuner, adjusted in the transmit mode to match 50 ohms, automatically produces a *conjugate* match between antenna and the receiver. So there is no power loss between antenna and Rx.

It is conventional in amateur receivers to mark the meter scale at 0 dB as S9. We have become accustomed to it. There's no need to change it. Almost without thinking about it we make allowances for the known scale-shape errors.

BUT WE ALL KNOW THE METER INDICATES RECEIVED SIGNAL *S*T*R*E*N*G*T*H*.

STRENGTH MEANS POWER.

AND POWER = WATTS.

If the receiver has an input resistance of 50 ohms then, according to Ohm et al, at S9 the receiver input is 50 micro-volts. But we don't want to know that except for calibration purposes. We are really interested in signal strength. In principle the meter can be calibrated to indicate received signal strength correctly whatever its input resistance may be.

Take a look at modern transceiver maintenance handbooks. Calibration at the low end of the scale is not perfect. But that's the fault of the meter/receiver manufacurers - for obvious reasons they are reluctant to make minor modifications to the conventionally long-accepted meter scale-shape. A more accurate S-meter has to be paid for. But it is accurate enough as it is.

If you have a vintage 1939 model with a bent needle which refuses to be calibrated it is not fair to blame either the standard or the unfortuate news-bearer. ;o)

And yes, I know what AGC is. It is that circuit which fortuitously produces an approximately logarithmic scale shape needed for S-meters. It costs only money to improve it.

Out of curiosity, who besides Reg has an amateur receiver that allows adjusting an S-meter to 6 dB per division? (And I don't mean a single point adjustment for S9, which has nothing to do with dB per S unit -- most receivers have this capability.)

How much room do I need for a rohn h50 and all the guy wires. I have a 30x60 or a 40x70 maybe a little bigger back yard, will that be big enough. Could I go with only using 8 guy wires on the top and bottom sections of the antenna mast and would it still be stable, or should I use more guy wires. Where can I get info on how to guy a antenna mast.

i would check rohns website not sure what it is right off hand but they
have a site with all the info you could possibly want
now on my rohn 25g tower i had only one set of wires at about 30 feet and
it worked well i had a tilt over base on it and 4 11 ele yagis stacked
for 2 meter SSB and 2 4 ele yagis stacked for 2 meters FM
and there was no problems
also becareful some areas of the country you have to get a permit to
install the tower and in order to get the permit you need to get the
installation engineered which is pricey
good luck

I have several Collins S line receivers that do not fair to bad in the S meter department. It has
been awhile (years) since I ran calibration curves on them but from what I remember they
tracked pretty well over about 3/4 of the scale. With S9 being 100 microvolts as the starting
point each S unit is pretty close to 6 DB as advertised. Over S9 the 10 DB marks fall pretty
much in line until getting up to around 50 over. The low end S1, S2 are, if I remember, deviated
from the 6 DB a little..
I used to use those receivers with calibrated attenuates ahead of them to make rough antenna
measurements. Once I ran a calibration curve on the meter I kept a sheet of paper with the
actual verses meter reading chart (a correction chart). I made one for each band as gain was a
little different on each. If trying to make a meaningful signal measurement, keeping a few DB of
attenuation switched in helped the antenna match.

There are no calibration adjustments other than meter zero and IF gain in those receivers. But
they do track as well as any receiver that I have seen.

6 DB per S unit used to be the standard years ago I think. Then somebody got the idea that if
dumb hams saw the meter kick up higher with a weak signal they would think that receiver was
"hotter" than the others and buy it! I guess it worked. How many times have you heard
comments about the "dead S meter" on some receivers or "boy is my new receiver ever hot"
"you guys are 15 DB stronger on the new one than you were on the old one". "This thing is
really sensitive".

O well, we did it to ourselves again.

Keying a transmitter and determining the reflected Vs forward power allows one to calculate a SWR.

When you key the transmitter the second time and recalculate, you now have SWR's. I heard it on CH 19 so it has to be right.

Hi Alex,

I'm building one now, but the design isn't quite ready for prime-time yet. This antenna should tune well below 40 meters, so might be a little overkill for you. But it will be fairly efficient on 40.

I can tell you it is around 7 meters in circumfrence. I have made a four pronged trombone capacitor (two prongs in series-two in parallel) using 19 mm copper pipe for the loop and outer part of the cap, and 13mm pipe and mylar dielectric for the other part. The cap has around 300 mm travel.

The shape is octagonal. The pipe is soldered together.

The motor to adjust the cap hasn't been chosen yet. HOpe this helps a little.

Good that people publish their experiences, but in this artice he says
in Figure 1. ' 3/4 lambda' in size. On the other hand G3RXO says he
used a 9.2 m high dipole. This ends up in a max. wave length of 12m.
Later he mentioned he used it for 7 - 21 Mhz (?)

If he would used a simple wire of any reasonable length with a tuner
it would most probably end up with the same results.

I3VHF can also provide his suggestions about the recommended and not
recommended installation sites, based on the extensive tests he
performed in the past years.
I used the BABY for a year at 1 m over ground, in a very poor location,
but it worked reasonably well, from 40 to 10 meters (here SWR was more
than 1.5, but a lot of iron wires were in the environment).

The basic control box displays an indication of the capacitor position,
but you cannot take for sure such a number. A simple humidity variation
change the resonance point from the evening to the following morning,
but the displayed number isn't changed and you don't know in what
direction the resonance point has moved.
The automatic tuner ATU do automatically what you have to do manually
using your TX at low power out and the manual control box.
The great advantages are:
- the TX isn't needed anymore
- you don't have to ask yourself "where is tuned now the loop?"

in order to know in what direction you have to start the motor.
You simply have to digit the frequency and another key to start
the tuner
- the emitted signal during the tuning is 12dBm max, which is
completely irradiated only when the loop is tuned, for a few seconds
in the worst case
- the tuning process takes the minimum time allowed by the loop
electrical/mechanical characteristics
- future version will be directly interfaced to the computer port of
(CAT) the currently commercial available RTX, and will have a direct
input to read the LO frequency for the homebrew or older RTX
- once you will try it, you will not go back to the manual controller
anymore

BTW, the commercial ATU is derived from the loop ATU I have build
a few years ago for my homebrew antenna.

> ï¿½ce type d'antenne permet il rï¿½ellement de pratiquer une activitï¿½ de
> radioamateur? Quelles sont les bandes de frï¿½quences les plus appropriï¿½es?

Two wavelengths is far too much for me (unless we're talking about UHF
wavelengths...).

The .06m distance seems much more practical to me. I can use a bigger
one, but its great to hear that this is the recomended minimum.

Thanks Ian and the rest !!!

"Two wavelengths is far too much for me (unless we`re talking about UHF wavelengths...)."

The UHF antenna has little effect on the VHF antenna, so you are talking UHF wavelength, which is about 70 centimeters. So, two wavelengths is 1.4 meters. As I said, amateurs are known to get away with smaller spacing.

Does anyone have any specs. or software to help me design a discone antenna. I want to experiment with a discone that will operate from the 12 meter band up to 10GHz. I prefer specs or a design program the uses radials not solid cones or discs.

Thanks!

If I remember correctly, the Clothesline antenna was in "CQ" a few
years ago. Picture a folded dipole with pulleys at each end so it
can be moved like a clothesline. The feedpoint will move off-center
and therefore the feedpoint impedance will change. The author claimed
that a resonant point could be found for each band by re-positioning
the feedpoint. It's a cute idea, but I like my tuning method better.

All the equations can be found in the ARRL Antenna Book (and other places).

The equations are simple.

However, since discones only work over a frequency ratio of about 5:1 and
you are asking for over 400:1, first you must get a good supply of
unobtainium with which to build it.

I'm currently looking for a antenna positioning system. The idea is to compensate multipath influence on antenna pattern measurements by spatial averaging at the receiver. I'm thinking of somehting rotation or a x-y positioning system. Positioning should be performed fast. Does anybody know a good EMC product which could perform this task? Also a list of companies doing such products is very welcome. Thanks!

One of the capacitors should be set to MAX C, i.e. minimum impedance. There will only be one solution then and it will be the best you can achieve with that tuner. Which capacitor it is that is set to max will depend on whether the reactance of your antenna is capacitive or inductive at the frequency of operation. Even better if you can bypass the 'unused' cap altogether.

From: Mark Wunderman <markwunderman@sprintmail.com>
Message-ID: <3D9204B0.80907@sprintmail.com>
Source record: 134152

The top portion of my Kenwood MA-700 antenna fell off and I want to replace the missing section. The dimension I need is for the straight piece that fits into the top of the coil and is fastened there with a set screw. If anyone can tell me the length of the top portion, from the top of the coil to the ball on the tip, it will save me a lot of effort trying to home in on the right length with a SWR meter.

Thanks in advance for any assistance.

Not quite. Which capacitor is set to the greater capacitance will
also depend on whether the load Z is higher or lower than the input Z
(typically 50). Furthermore, max capacitance at either end is not
always the optimum solution.

|Even better if you can bypass the 'unused' cap altogether.

No, then you have an L network, over which you have no control of the
loaded Q, which is determined entirely by the two impedances and which
might well require completely impractical component values.

For example, consider a C-L-C tee network with C1 and C2 = 10 to 300pF
(Q=500) and L = 1 to 100 uH (Q=100).

CASE 1.

The frequency is 3.7 MHz and the load Z = 100 +j0.

A nearly optimum solution (minimum insertion loss and SWR<=1.02) is
thus:

C1 = 297.5pF, C2 = 219pF, L = 4.21 uH. The SWR = 1.02 and the
insertion loss = 0.25 dB.

We got lucky here since the max value of C1 is just about optimum.

Setting C1 = 300pF (max), the results are:

C1 = 300pF, C2 = 221.3pF, L = 4.19uH.

Now let's short out C2. The best we can do is:

C1 = 300pf, L = 6.94uH, SWR = 4.6 and insertion loss = 2.4 dB.

To get an optimum match, we need C1 = 872pF, L = 4.38uH.

CASE 2.

The frequency is 3.7 MHz and the load Z = 25 +j0

An optimum solution is:

C1 = 224.5pF, C2 = 297.8pf, L = 3.7uH. The SWR is 1.02 and the insertion loss is 0.49 dB.

Once again we were "lucky" and setting C2 to max is nearly optimum.

Now let's short out C1. The best we can do is:

C2 = 300pf l = 6.64uH, SWR = 16 and insertion loss = 6.8 dB.

To get an optimum match, we need C2 = 1730pF, L = 2.18uH.

So in both cases of turning the tee network into an L network, impractical capacitor values are required. And another thing...if you think that shorting out the capacitor set to the higher value is correct, you are mistaken.

Note:

I used ARRL Radio Designer software to do these calculations. This is no longer available, however Ansoft has a student version of their Serenade program available as freeware at:

http://www.ansoft.com/about/academics/sersv/index.cfm

It is even more powerful, albeit with a steeper learning curve.

If you have MS Excel, an even better way to play with this stuff is to download Dan's program XLZIZL.xls at:

http://www.qsl.net/ac6la/XLZIZL.zip

Source record: 134154

Hello Will,

In principle no more than two variable tuner components are needed to match the antenna to the transmitter.

But to avoid inconvenient component values and to avoid having to interchange component circuit locations in the middle of tuning operations, three components may be used used in the form of a T or Pi network, high-pass or low-pass confuration.

The C-L-C high-pass T-network is the most common configuration.

Whenever there are 3 or more variable components there is an infinite number of alternative settings to produce an impedance match. The only difference between them is power transmission efficiency.

Since, for practical purposes, tuner loss occurs only in the inductance then highest efficiency occurs when the inductance is set to the lowest value which allows a match to be achieved by varying the two capacitors.

Similarly, in other configurations least loss occurs when inductors are set to the lowest values which will allow an impedance match. Very often the efficiency limitation is due to the maximum available settings of capacitors.

(PS : An L-network always has higher efficiency than its corresponding T-network. But in most circumstances the difference is very small.)

Download in a few seconds programs T_TUNER and L_TUNER from website below.

5665. Correct Ladder Line Length for 88 ft Doublet?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-25 21:19:06 UTC
From: Dave Alden <dalden@comcast.net>
Message-ID: <m294pug9m3bcmdqvomprmds5qu2ef0nau5@4ax.com>
Source record: 134155

Hello!

I just built an 88 ft. Doublet (44 ft. each leg) center fed with 450 ohm ladder line. The center of the antenna is at 30 ft., with one legs end at 12 ft and the others at 6 ft off the ground. I had no way to make it a flat top so it is like an inverted V. The ladder line is about 40 feet long and goes directly into the shack and connects to a 4:1 Balun on the back of my AT-11MP Auto tuner which feeds my Icom 706mkIIg.

The antenna is almost a flat match on 20M and auto tunes pretty easy on the other bands from 80-10M.

The problem is that with the ladder line coming into the shack, I get RF into my computer speakers and any other radios that happen to be on when I transmit.

The solution would seem to be to move the balun outside, as for away from the shack as possible (in a tupperware container) and run coax from the balun into the shack.

The question is: Is there an optimum length for the ladder line? How much shorter can I make it and not affect the performance of the antenna? Ideally, shortening the ladder line to about 25 feet would work well from an installation standpoint but I don't know how this would affect the antenna.

By the way, this antenna receives MUCH better than my old Gap Challenger DX vertical. I have not had much chance to evaluate how it works on the transmit side but I expect it will probably be pretty good.

Any comments would be appreciated!

Dave Alden WK8F dalden@comcast.net

One caveat. This is true only when the Q of the inductor does not
change with value. In the usual case of a roller inductor or
switched-tap inductor this will not be true. In particular, roller
inductors generally have greatly reduced Q at the lower inductance
settings.

Since the operational solution to this problem can be complex, no pun
intended, my oft repeated suggestion that a relative output indicator,
as well as the input SWR meter, be used during adjustment is repeated
once again.

A clarification.

The above insertion loss figures are not the loss in the components per se, which are actually quite small, but the total loss which includes the effects of mismatch.

Before someone squawks that mismatch loss isn't "real" and that we use conjugately matched sources, blah, blah... a usual reason for using a tuner is that the transmitter is not adjustable and will deliver lower power into a non-fifty ohm load.

It is possible that a particular transmitter might love a 16:1 SWR and put out full power into it, thus negating the 6.8 dB mismatch loss, but I doubt it.

OK.

Something I don't quite understand is why the UHF antenna has little
effect on the VHF one and not vice-versa, since they are similar in
length.

Does the UHF antenna have a smaller capture area while being almost as
big as the VHF yagi ?

Thanks Richard

there are lots of companies that make linear actuators and all sorts of positioning systems. check the thomas registry or just search the web for actuators or positioning systems. you will have to know how heavy an object you want to move, range of motion, and just how fast is 'fast' to make a choice. also the operating environment would be important.

Hi OM,

The single greatest point of significance lost to all is that your
proposed antenna will be deaf to terrestrial signals over 98% of its
proposed bandwidth. Same is true for the offered dipole - except in
two exceedingly favored directions.

If you build for a match at the lowest end of the service range, the
size of the antenna at the high end (for extremely wide banded
designs), in terms of wavelength, almost guarantee end-fire
properties. For the discone this is straight up even by the time you
are bringing it online for a 2M contact.

Roberto, EB4EQA wrote:
"Does the UHF antenna have a smaller capture area while being almost as big as the VHF Yagi?"

I am ignorant of the antennas being discussed. My remark that the smaller antenna is a smaller disturbance to the larger antenna than vice versa is based solely on common sense and my experience with multifrequency items having a mutual impedance.

The reason you may need 2 wavelengths separation is in part due to dissimilarity between antennas. Identical antennas might have their elements aligned for axis sharing between antennas. Radiating elements sharing the same axis have nulls at their ends which reduces the coupling between the elements. Some writers estimate the difference in coupling between antenna elements sharing the same axis and those having parallel elements at the same distance as 10x as great for the parallel elements.

Since dissimilar antennas can`t have all elements in one antenna sharing an axis with a corresponding element in a similar antenna, some elemennts have a component of coupling from a partial broadside or parallel presentation to each other between antennas. This increases coupling, and this can be offset by wider spacing.

Interaction won`t keep antennas from working. It means impedance and directionality are affected in each antenna by the presence of the other antenna. Many multifrequency antennas are really several antennas sharing the same boom.

Best regards, Richard Harrison, KB5WZI

5674. Re: Correct ratio for design of loading coil

There's no such thing as the 'correct length' of a loading coil.

In an antenna, if you are looking for maximum loading coil Q you will notice no difference between Length over Diameter ratios. It's an overated and over-discussed topic. Ignore your antenna 'text books' written by OW's.

There is one aspect which might make some small difference. The capacitance between the antenna wire on one side of the coil and the wire on the other side of the coil is in parallel with coil's self-capacitance. It is desirable to minimise the sum of these two capacitances. They have the effect of 'detuning' the coil, increasing its effective inductance, unnecessarily increasing the local circulating current and so increasing losses in coil RF resistance.

It is much better for the current flowing along the wire into the coil to be nearly equal to the current flowing along the other wire out of the coil. This common current then flows where it is wanted - through the radiation resistance of the antenna wires. (It should not be forgotten the coil itself has a radiation resistance proportional to ts length.)

So the longer the coil, the smaller is the capacitance across the coil, the smaller is the circulating current around the coil and the more efficient is the radiating system.

It is difficult to calculate and estimate the overall effect in a particular situation. It depends on the overall dimensions of the antenna and on the ratio of overall wire length to coil length rather than on the conventional coil length to coil diameter ratio. Allow your thoughts to stray to what happens along a helically-wound antenna.

But intuition indicates you won't go far wrong by making the (Coil Length) / (Coil Diameter) ratio between 3 and 4, and using a large diameter coil with fewer turns of thicker wire. It's very non-critical. It won't win you many contests.

Sorry to use the word 'coil' so many times in order to make matters less ambiguous and more clear.

> The idea is to compensate multipath influence on antenna
> pattern measurements by spatial averaging at the receiver.

One obvious problem with your suggested approach is that you're unintentionally assuming that the troublesome reflections don't follow you, and your antenna positioning system, around the room. Will your antenna positioning system be RF transparent (or at least wrapped in RF absorbing material) ?

I thought that the favoured approach to ultimately solving this problem was to use a pulse waveform, sample rapidly and catch the direct wave before the reflected wave(s) arrive (via a longer path - by definition) to screw up your measurements. With suitable algorithms, it should be fully automatic and self checking. You could add a Barker code and amplitude correlation to make it even better.

If you're in the EMC field, you must have heard of the Item journal. Here is their webpage - perhaps it will help you to find some further info.

http://www.rbitem.com/home.asp

Good luck.

If all you are doing is SWL, I think a ham vertical will be a waste of time and money.
Your random wire will likely be as good or better in most cases. The only reason I could think of to use a vertical, would be to have an antenna that is maybe better for long haul dx on the lower bands. And in that case, any vertical piece of wire would probably do as good as a tuned vertical. You don't really need gain, and as you state, you don't want to turn it anyway, even if you had a gain antenna. A short vertical sure won't have any gain compared to a 40m random wire. As for SWL verticals, any old piece of radiator would do in your case. Wire hung from a tree, or tubing supported from the ground. There is no real need to tune it to resonance unless you want to pump up the S meter. The S/N ratio will likely be about the same. If I did want to tune it, I would just stick a coil at the base, and have clips to change bands. A 40m meter long ramdom wire is a fairly "real" antenna for SWL use. It's going to outdo an appx 8-9 meter tall vertical most of the time I bet.

Mine works great. I have a full wave 80 meter loop with
a tuner and can work all bands with it. Most of the time,
the MQ2 outperforms the loop on 20 through 10. There are
some locations that the loop hears as well as, and sometimes
better than, the MQ2.

Would I buy it again? Absolutely - in a heartbeat.

>
>Thanks!
>KC9BNY

Check the RSGB VHF/UHF Manual. They give design equations for
discones. As others have pointed out, you won't get the coverage you
want with one antenna, and in the upper half of a discone's frequency
range, the take-off angle is very high. A Google or Teoma search on
the net will also turn up a lot of sites with info, including a couple
for building discones for the 800MHz - 2.4 GHz range. These are small
and easy to make.

In general (from the RSGB VHF/UHF Manual, 4th ed, pp 8.39 - 8.40)

A is the length of the cone elements, a quarter wavelength at the
lowest operating frequency

B is the overall disc diameter, 70% of a quarter wavelength

C is the diameter of the top of the cone. This will be decided to some
extent by the diameter of the coaxial cable. 0.5 inches is commonly
used.

D is the spacing of the centre of the top disc to the cone top, 20% of
C, or 0.1 inches for 50 ohms.

This assumes a 60 degree angle of the cone.

You can make good discones for higher frequencies (1.2G - 3G or so)
using 0.141 semirigid line and attaching a cone made of copper foil to
that. The spacing between the cone top and the disc gets a bit touchy
to keep a 50 ohm impedance. Cut-and-try with a signal source and a
coupler or network analyzer helps if you're going to be using the
antenna to transmit.

You can make pretty good log periodic antennas with fairly wide
coverage using material such as duroid (low dielectric printed circuit
board material used at microwave frequencies). There are usually

people selling small pieces of duriod on eBay.

have fun--

>Does the UHF antenna have a smaller capture area while being almost as
>big as the VHF yagi ?
>
Yes. The width and height of the capture area are each measured in wavelengths. This scaling factor is larger than the effect of electrical boom length on capture area.

The objective of stacking at half the recommended stacking distance for two of the 432MHz yagis (as a minimum) is to place the 144MHz yagi outside of the capture area of the 432MHz yagi. This avoids disturbance by the elements of the 144MHz yagi, which are electrically quite large at 432MHz.

However, the 432MHz yagi will still be *inside* the physically larger capture area of the 144MHz yagi. This matters much less because the elements of the 432MHz yagi are electrically small at 144MHz.

That's the short version. Full details are on my web site.

5692. Ideas on copper wire stretching and sagging

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-26 11:01:24 UTC
From: mike c <md_removeunderscores_cola@evenlink.com>
Message-ID: <MPG.17fcb310f1a6bcd498968a@news.evenlink.com>
Source record: 134031

Hi:

i was lurking around prior to posting a question and saw the stretching subject.

here's what i'd do and not worry about tension.

why not just tension a length of poly rope and suspend your wire underneath with just enough tension to make it look nice? when i pull cable wire, the more rollers i put out on the strand, the less tension i'm pulling when i'm 2500 ft out. so the more suspension points, the better.

hint: loose lash the wire to the rope on the ground and tension the rope.

how's that for bandwidth efficiency? ok, i'll use some more...

In CATV construction, I once encountered a manual which prescribed pre-tensioning strand so that when sagged in, it wouldn't stretch much more in service. now done incorrectly, that could lead to fatigue and premature failure.

the mere act of lashing cable to the strand sometimes stretches it plenty and it should have been tensioned by the strand crew so that the cable weight would leave it sagged right. This method is called experience.

one thing not mentioned in the OP was that when it gets cold out, the wire contracts, the sag is lessened, and the tension increases. now add ice. in peoria illinois, a strand crew sagged in a road crossing one winter and a fiber crew cabled it. come summertime, the span sagged and an 18 wheeler took it out :-) TCI was pissed off. They also had a great day in Ft. Worth Tx when two guys had a shoot-out and hit an aerial trunk amp. texas can be fun. TCI? Telecommunications International (or Inc - i forgot) actually it's Things Change Instantly - like your contract or the job specs.

TCI had a drop wire running to a house that was so tight, when i climed the pole (imagine the pole swaying back and forth as I get higher) it set off the vibration detector for the alarm. no monitoring - no cops. hell, the neighbors didn't even come out.

another way would be to just attach the wire at one end to a fixed point, attach the other end to a rope. run the rope through a pully (i saw one attached to a pole i was on once, but the rope was tied off at the base of the pole. luckily the op kept it out of my

climbing space.) hang just enough weight to get your sag (accounting for ice and wind) and leave it like that. when the wind blows, the weight rises, the sag increases, and tension is the same except for the initial impulse of the wind force. once equilibirum is reached, the tension is still that of the weight. when ice forms, same deal, the wire tension is reduced by virtue of the increased sag and replaced with tension caused by the weight of the ice.

is all of this too simple?

I stand corrected, I think, but a couple of points.

1. I have never yet seen a variable inductor with constant Q. Inductance varies with N^2, loss resistance with N, approximately, so your models are incorrect. Q at low L will be _much_ less than Q at high L.

2. In both cases you have shorted the wrong cap. A shorted cap is the equivalent of an infinite cap. I.e. impedance is zero.

I'd be very interested in your results with these corrections, Wes. I don't have the software.

but the flexing would be greater at the bottom of the stick which is
why a mobile spring base is at the base, not the top. the paint we
used in army basic training seemed to have a rubbery feel when dry.
it was water resistant an d i got the impression that it would stand
up to expansion/contraction well.

Darn radials....

If you mean insulated...well, most ham installations END UP with insulated radials as it's hard to stop oxidation of copper and aluminum wire.

The main benefit to using insulated wire is that it let's you control the 'insulation' without letting the wire totally oxidized and thus become a very poor conductor. It loads a small bit too.

Of course, over time, water finds itself inside the plastic and we all return to dust;-)

From: Andy Cowley <andy.cowley@uwe.ac.uk>
Message-ID: <3D92FD9F.7162E053@uwe.ac.uk>
Source record: 134041

I've been playing with this using the T match emulator at

http://fermi.la.asu.edu/w9cf/tuner/tuner.html

as posted by Peter O. Brackett. Thanks Peter.

It auto tunes to set one cap to max. whatever value
it is given for antenna impedance or max cap value.
So its autotune function agrees with me. I've fiddled
a bit and I can't improve on its settings. As written
it doesn't do L matches so I emulated it with infeasibly
large capacitor values and lo and behold it still set
one cap to max for all the antenna impedances I tried.
So I think my advice was good. Maybe there are some
residuals causing errors in the s/w you are using?

I'm not enough of a mathematician to do this from first
principles but I still think my advice was correct. Can
you show an example of a real world antenna impedance
(r >= 10 ohms <= 1000 ohms, and |reactance| <= 2000 ohms)
where both caps are set more than 10% away from their
max value? (10% to allow for the possible errors in one
of the software models). I can't find one.

Maybe there are places where this is needed due to the
limitations on the ranges of the coil and caps, but in
general I'm right.

We are after all trying to solve a transformation of
only two independent variables, so the minimal solution
must involve only two variable components.

i can't find the JC post was in the 2m tuner thread. i searched the group articles. makes it hard to follow the thread.

one thing it seems you're doing - sometimes your replies are to the OP or someone other than who the quoted post applies to, confusing things further.

i just saw a JC post elsewhere in the antenna group. there were multiple cases of this in the 2m tuner thread. maybe the Newsfeeds.com is responsible for losing it. or theres a crossposting prob from rec.radio.amateur.homebrew the OP seems to have cross posted ok. maybe JC isn't crossposting properly for some reason. i see my reader requires me to manually add crossposts.

"Oh, conjugate matches? Complex conjugates?"

Sure, as Walter Maxwell, W2DU has always said, to get the most from a transmitter, the load must be the conjugate of the transmitter`s internal impedance. Also, in an ideal system, the impedance looking in opposite directions anywhere you might break the transmission system are conjugates of each other.

See: King, Mimno, and Wing, "Transmission Lines, Antennas, and Waveguides",page 43. All three authors were Ph.D.`s at Harvard in 1945 when this was published by McGraw-Hill.

ha! that's what i suggested for a demo that had to be transported via airline with the presenter. he would've had to pack two radios mounted in cases with demo circuitry, a scope, 2 2m 5/8 verts, and the ground planes.

poor ground plane was messing up my propagation and swr, as mentioned in that 2m tuner post. i had one unit in my van for testing, but the one at the lab wasn't doing squat. or bench press for that matter :-)

it's great to run into people that think along the same lines as i do.

BTW, remember that a 1/4 wave or 5/8 wave vert's impedance is based on a theoretical mirror image underground. so if your ground conductivity is poor or the ground rod is not acting under the radiator (as in the case at the lab i mentioned,) then yer screwed.

who cares about what came 1st - the chicken or the egg as long as we have the wire.

Dave, WK8F wrote:
"Is there an optimum length for the ladder line?"

Yes, as the ladder line is often transforming an antenna impedance which is too high to something more compatible with your radio.

See:
http://www.qsl.net/w5dxp
These are Cecil A. Moore`s web pages which include a method which may eliminate a tuner and replace it with specific lengths of ladder line.

For a similar approach which never the less retains the tuner, see Figure 20 on page 486 of the 18th edition of the "Radio Handbook" from Editors and Engineers, Ltd., William I. ORR, W^SAI, Editor. The Figure 20 title is: "Dimensions for Center-Fed Multiband Antenna".

With an in-between dipole length and a lower than anticipated antenna height, your results will vary, but you will get a picture of what is happening.

In theory there are no impedances that cannot be matched by shorting either C1 and C2, and using the inductor and the other capacitor as an L-network.

It's also true that the L-network will always have the lowest possible loaded Q for transforming between two impedances. Regardless of the network used, there is a minimum necessary loaded Q to match Z1 to Z2. The L-network can only operate at one loaded Q, and it's that minimum necessary value.

The CLC T-network will always operate at a higher loaded Q than a plain L-network, because it is effectively two step-up L-networks back-to-back. To get from Z1 to Z2, you have to step up through a notional intermediate impedance Z3 which is higher than both, so the loaded Q is higher than the minimum that is possible with an L-network.

>Maybe there are places where this is needed due to the
>limitations on the ranges of the coil and caps, but in

>general I'm right.
>
>We are after all trying to solve a transformation of
>only two independent variables, so the minimal solution
>must involve only two variable components.

In theory, yes, but there are lots of *practical* limitations. The assumption of constant Q with a variable L has already been called into question.

Another practical limitation is that L networks are quite poor at matching impedances that are already close to the target, at the centre of the Smith chart. This is partly because the L and C values become unachievable, but there's another even more important reason - the matching ranges of the two different kinds of L networks (CL and LC) do not overlap. When you cross that boundary, the wrong kind of network will not match with *any* values of L and C.

The big problem is that the boundary passes right through the centre of the Smith chart! This means that some antennas can require different kinds of L-network for matching at opposite ends of a band, especially if the antenna has been adjusted to give a good 'natural' match in the center of the band.

In contrast, the CLC T-match will handle such situations smoothly... but at the expense of loaded Q and efficiency.

G3LNP published a nice practical solution in Radcom a few years ago. When either C reaches its maximum value, it operates a switch that shorts it out completely - the T-network becomes an L-network, of the right kind. The downside is that it has to be used with a roller L, or one with a lot of switched taps.

I had the same idea but in my case I have thought about using a nylon rope
instead. I am wondering about the influence of rain in this case,
particularly because the rope woud be much longer than the dipole itself.

Have an idea or experience ?

>when I transmit.
>
This is not surprising, because your doublet is very asymmetrical with respect to ground, and therefore common-mode currents flow down the ladder line and into the shack.

A good first step would be to raise the 6ft end to 12ft... it's not a good idea anyway to leave the hot end within such easy reach.

>The solution would seem to be to move the balun outside, as for away
>from the shack as possible (in a tupperware container) and run coax
>from the balun into the shack.
>
You have the right idea... but possibly the wrong balun. You don't need a 9:1 balun with 450-ohm ladder line and a doublet, because the load impedance at the bottom of the line is never 450 ohms. Try a simple 1:1 "current" or "choke" balun made by coiling the coax out there into a flat coil (much cheaper than ferrite), and connect the ladder line directly to the far end of the coiled coax.

If the tuner will handle the new set of load impedances, you're flying. The SWR on the coax will be pretty fierce on some bands, so you should use at least RG213 to keep the losses down. Since the coax length will only be about 15ft (plus what's in the coil) the losses won't be too bad.

Alternatively, since it's an auto-tuner and doesn't need you around, the best solution is to move that out to the Tupperware box, and put the 1:1 choke balun on the output side.

If you still have RF in the shack, try another coil choke just behind
the rig.

It can all be calculated, but try it and see...

>mike c

Hi Mike,

The tension of the flex is greater at the base, but the flex itself is
an indication of the resolution of stress into deformation, and that
occurs well above the base with a vengence - otherwise the structure
would tip, or break. The spring at the base is a method to overcome
tip or break (i.e. the base does not flex well at all without it).

|
|WRONG CAP SHORTED !!!!!!!!!!! SHORT C1 AND RECALCULATE With C1 = infinity.

Nope. See my earlier comment below.

In this case, the load Zl (100+j0) > Zin (50). Therefore, the first
matching element must be in parallel with Zl. Shorting out C2 places
L (~4.3 uH) in parallel with Zl, and neglecting Q for a moment to keep

the numbers easy, the result is 100||j100 (Which should properly be
dealt with as an admittance, but we'll leave it this way for now).
This combination has a series equivalent of 50 + j50. Adding 50 ohm
of capacitive reactance (~860 pF) yields the desired 50 +j0.

[snip]

|> So in both cases of turning the tee network into an L network,
|> impractical capacitor values are required. And another thing...if you
|> think that shorting out the capacitor set to the higher value is
|> correct, you are mistaken.

|I stand corrected, I think, but a couple of points.
|
|1. I have never yet seen a variable inductor with constant Q. Inductance
|varies with N^2, loss resistance with N, approximately, so your models are
|incorrect. Q at low L will be _much_ less than Q at high L.

I agree with your first statement. In fact, I said earlier in this
thread:

"One caveat. This is true only when the Q of the inductor does not
change with value. In the usual case of a roller inductor or
switched-tap inductor this will not be true. In particular, roller
inductors generally have greatly reduced Q at the lower inductance
settings."

However, the models are not incorrect. Changing the inductor Q will
affect the values of the elements and the network loss; however, it
will not change the required topology.

|
|2. In both cases you have shorted the wrong cap. A shorted cap is the
|equivalent of an infinite cap. I.e. impedance is zero.

Answered above.

|
|I'd be very interested in your results with these corrections, Wes. I
|don't have the software.

There are no corrections to be made, so the results are unchanged.

Sorry Will; I intended my original post for the group as well, Keith, VE3JKC

Hi Will; I don't think I've seen any mention of the program that comes with

the ARRL Antenna Book. It's called AAT for Advanced Antenna Tuner and will

allow one to analyse two configurations of "L" the "PI" as well as the "T".

You can change any parameter including "Q" of components and it will allow you to set component values and look at loss, component stress etc. However

you do need to know the termination complex impedance of your antenna system. I have found it very useful in both designing tuners as well as setting them for minimum insertion loss. Good luck. Keith, VE3JKC.

Hi again Will; Forgot to mention in my posting that there is another excellent program on the Antenna Book CD called TLW for Transmission Lines Windows. It May be a little easier to use to answer your initial question. It does however start at the antenna and work through the transmission line and then allows you to design your tuner or at least assign values to the three components of the "T" tuner. It also will give overall tuner loss with various component values and component stress. ie; coil dissipation and capacitor voltages. These programs are written by Dean Straw N6BV and if you get the 19th edition of the book it is the latest version of the software. Again, have fun, Keith, VE3JKC.

Source record: 134065

Hello, I bought a MFJ-941E Versa Antenna tuner and didn't receive a manual.
I did however receive a paper with some instructions typed onto it. I want
to connect a 300 ohm twin-lead to it. Here's the back MFJ941E :

http://members.rogers.com/alexsradio/mfj941e.jpg

The paper say "A jumper wire from the WIRE binding post, as indicated by a
dotted line on the MFJ941E, should be connected to one of the posts of the
BALANCED LINE. This couples the MFJ941E to the balanced line through a 4:1
balun."
Without a diagram showing the dotted line i'm stuck. Does anyone have a
Versa Tuner that could help me?

Thanks!

Just a thought

My preference for ham wire antennas is 2mm HDC (bare). If you compare say 6mm diameter polyester cable laid rope alone, it has a tensile strength about 30% greater than the copper and a wind resistance of 300% higher than the copper, so its wind survival speed might be around half of the 2mm HDC.

Use of a synthetic fibre rope as a catenary to support a thinner conductor might have more application if you were using very thin wire... but then you are probably doing that for stealth reasons and don't want to draw attention to it with a very visible fibre rope.

Just a thought

My preference for ham wire antennas is 3mm HDC (bare). If you compare say 6mm diameter polyester cable laid rope alone, it has a tensile strength about 30% greater than the copper and a wind resistance of 100% higher than the copper, so its wind survival speed might be just a little less than the 3mm HDC.

The synthetic fibre rope will deteriorate and quickly become inferior to the copper, so is less suitable for long term installation.

The different stretch of the rope and copper might raise some challenges for supporting the wire without breaking it when the rope stretches.

Use of a synthetic fibre rope as a catenary to support a thinner conductor might have more application if you were using very thin wire... but then you are probably doing that for stealth reasons and don't want to draw attention to it with a very visible fibre rope.

At the MFJ web site, I believe it is www.mfjenterprises.com
you can download manuals for most all of the tuners they make.

I've never needed a tuner for a normal 1/4 wave inv L. I have one up now, and it's fed with coax and no tuner at all. Has a good match. The only time I've used a cap in series was with an "extended" inv L of 185-190 ft long. I guess the length he wants to use will depend on the pattern he wants. A 1/4 wave has less overhead radiation than the extended version. Better for dx usually. But the longer antennas radiate more at higher angles, and many times are better for regional work. Usually a bit less ground losses also, as the point of maximum current is raised up off the ground with the 185 ft inv L. My present version is only a 1/4 wave. 125-135 ft??? or so..I also use a T vertical at times on 160m. It's actually my parallel 80-40-20 dipoles fed as a vertical. It has an overhead null like a straight 1/4 wave monopole would. MK

That can come in handy. I did a test once with my 989c tuner. I used
meters on both ends, etc. I found in my case, the lowest inductance
always gave the least loss, even with the possible lowering of the Q.
Didn't seem to matter much. I never did see an exception to this when
I tested it. So I always use the least inductance no matter what. I
found on the 989c, it's usually the "ant" cap that will be at max C.
Only in rare cases will it not be at max. On the other hand, the
"xmtr" cap, can be about anywhere. Usually about 1/4 to 1/2 range is

where it ends up. I don't worry about that. My method of tuning is to set the caps about 1/3 to 1/2 scale, and peak the noise with the coil. That gets in the ballpark at first. And then roll the inductance back bit by bit, retuning, until I can't get a decent match. Then I roll back to the point where I have just enough coil to match. Most of the time, at this point, the ant cap will be at max. I consider that the best setting, and according to my tests, always gave the least loss. I found using too much coil can cause up to 20% loss in the tuner. I found that using the least inductance, and "usually" max ant cap, gave a loss almost unnoticable on an average watt meter. Very low..There may be strange exceptions, but so far, I've never seen one with the 989c. MK

I once insulted my radials by hitting them with a weed-whacker where they connect to my vertical.

After many apologies (and some first aid), we eventually made up. The good news was that they didn't seem to hold a grudge for very long.

Sandpiper used to have the stuff they use to make their own antennas
available quite
cheaply.

Sandpiper is one if those businesses that could benefit from a web site.
Even just a facsimile of their print catalogue would be useful.

If you just want small amounts you will probably find your local B&Q stock it- mine does. It isn't the cheapest way to buy it but it is convenient!

If you want more just try Yellow Pages under Aluminium Stock Holders- they will usually supply in small quantities or off cuts for cash.

I've only ever found Al rod and that's only at the B&Q Warehouse stores (not the smaller ones).

If this is the stuff you're talking about, they are appallingly bad at re-stocking. I emptied out all the B&Q's in the London area about 18 months ago :-(

Kris,
After looking at the advertisements, it seems like
the 'biggest' difference is in polarization. Do you
want horizontal, or vertical polarization? I didn't
take a look at prices for the 'loops', so that may be
a bigger consideration than I think(?).

Well my local 'normal' B&Q does rod, tube, and strip in Al, brass, and some composite material (plus others not so interesting to hams). The local radio club did 'clean them out' of the 6mm tube when a load of them built the "BRAT Hunt DF Antenna" but they did recover ;-). Poetic really, the club DF hunts always start in the local B&Q car park.

Source record: 133992

Trees,
Okay, I tried it in an antenna modeling program,
don't have any place to 'hang' a vertical. After
going through several hundred 'runs' with demensions
from the given length, to well over a 1/4 wave length
at 7 Mhz, 'NEC' just doesn't agree with your findings.
Input SWR ranged from a low of 2.9 to totally rediculous
values.
I realize that the 'testing' that I've done isn't
exactly 'definitive', but it does lead me to believe
what I said once before, "If it seems too good to be
true, it usually is.".

I used an EDX-2 with my DX-77T for 3 years.

The tuner is an unbalanced L network tuner, that can change its configuration for high or low impedance.

I never used it to feed an end fed wire, which is what it is sold for.

I used it to feed 300 ohm balanced line to a dipole, and a loop. I did NOT use my home brew 1:1 Balun as I found it just added losses.

In one configuration I found I had some ground currents, so I used a few ferrite tube chokes on the control line and the feed line to control that.

In an A/ B comparison, I found that my Johnson Matchbox was noticeably better in received signal strength on one band, I don't recall which one. This was probably due to losses in the tuner at some matching configurations.

For "straight through" you power down the radio, then power it back up, with out using the tune feature. This often works better for out ob band listening than trying to tune the nearest Amateur band.

yes. nylon rope may stretch more. my step dad used a 1" nylon rope as a safety when lowering his 32' trimaran down his steep boat ramp. he had it tied off holding the boat on the ramp (stuck) and let off the winch. we pushed on the trailer and it went. the rope stretched (probably would be worse if rope were wet - my old partner had some and it performed poorly one rainy day) and the boat ended up travelling way too far for comfort and ended up slightly cocked on the trailer.

when i get a new poly rope, i always pretension it over night. i'll pull on the middle and tighten it as much as i can. this gets rid of the memory (espescially with the 1/4" stuff that comes in a bag) so i can coil it up neatly. i use the stuff for a throw line. i just put a CATV eyenut on the end, hold the coil in my left hand and swing the weight in a circle pointing at the tree. then i release it toward the branches i'm trying to get through. with practice, you'll amaze those who use crossbows or regular bows and you'll have a good strong line for pulling bigger stuff through.

i suppose nylon could be pretensioned also. if we'd done that with the safety rope, it might have stopped the boat sooner. in fact, the mule tape i use for fiber optic cable is nylon and eventually looses it's stretch.

> for supporting the wire without breaking it when the rope stretches.

uh, if you re-read my post, i suggested loosly lashing the wire to
the rope. the wire and rope will slide relative to each other. a
little slack in the wire ...

same situation with coax lashed to 1/4" galvanized steel strand. in
the winter, Comscope Qauntum Reach contracts so much that you need
expansion loops on BOTH end of spans greater than 100 - 150 ft
depending on the climate. the loops get almost totally sucked out in
the cold. if the cable becomes more tensioned than the strand, it
will oscillate. literally flops up and down on it's own. you can see
the standing wave on it.

add some springs (insulated from the wire, of course) to the ends of
the wire or something.

>

yeah. that thin wire windom on the pole i mentioned was real stealthy
with the spreaders and all. freakin' aerial cluster #&#@% was more
like it. the guy had a lot of stuff up there. it could all be seen
from the road to his back yard.

and if it's a center-fed, how invisible will the feed line be?

Although the information supplied with mine is scant, it does show its application for end feeding a vertical or wire (including advice on selection of radiator length). It does not show how to feed a balanced line.

You could use a balun to transition from the unbalanced EDX2 to a balanced load, but given that the EDX2 is designed to match a very wide range of impedances, the design of a balun that is not unduly lossy and does not restrict the impedance and frequency range of the tuner would be a challenge.

If you look at the circuit diagram, you might reasonably form the opinion that the earth terminal is meant to be earthed rather than connected to one side of a balanced load. Nevertheless, you will find plenty of OMs who will assure you that it (and others like the AHx and SGCxxxx) works just fine used on balanced loads, and that some have had to eliminate RF conducted into the shack on the feedline and control cable. I would not operate it in that way.

In my experience, the lack of information on the EDX2, especially alignment information, and the patent lack of interest in support of Alinco products by Alinco and their dealers is the worst aspect of the tuner. When I properly calibrated the detectors in mine, and rebuilt in in a new box when the original enclosure cracked up within a few months of purchase (http://u01.owenduffy.com.au/~owen/edx201.jpg), it works real well.

I use it frequently in a portable situation and it almost always achieves a match better than 1.2 (enabling full output power from the DX70TH) on any HF band on a 26m sloper that is 15m above ground at the high end and ground level at the EDX2 end. Whilst the sloper loads up on any band, it lacks the low angle radiation that is generally desired for 20m and up, but the high angle radiation is just what is needed for local contacts on 160, 80 and 40m. The 26m was chosen to not be within 5% of an odd or even quarter wave resonance on any HF band so as to avoid very high voltages impressed on the tuner at even multiples, or excessive influence of earth system loss at odd multiples.

> little slack in the wire ...
>

Yes, I saw your words... however my thought was that sometimes things that we set up to slide freely wind up binding and causing grief... so they are a challenge, though not impossible at all!

The rope idea is a good one for prototyping or portable work, no doubt about that, and I use it frequently. I am less inclined to use it as much in long term installations.

I do have a "semi-permanent" installation at a holiday cottage where a sloper attached to a substantial tree bough is tensioned by a weight suspended on a fibre rope running through a sheave block to the low end of the wire... always a concern and subject to frequent inspection to see that the sheave still runs free and that the rope hasn't developed too permanent a kink. In very strong winds, I have observed the wire pull 2m of rope out to allow more belly in the wire (which was almost horizontal). One day it will blow down - hence the "semi-permanant" status.

Cheers... Owen

5764. Would MININEC do this simple job accurately??

I'd like to model a simple flattop duoband dipole for 20 & 15. The dipoles would consist of parallel wires spaced six inches apart and fed in the center with a single 50 ohm coax line. Would a MININEC-based modeler be able to handle this scenario reasonably accurately or is this one of those situations MININEC does not handle well?

Standard MININEC has trouble with close spaced parallel wires. I don't recall if the spacing you mention is close enough to cause a problem with an unmodified MININEC program, but it might be. MININEC can be modified to handle closer wire spacing than the original, so if the program you're using has this modification, it should be ok. You'll also need to make sure the segment length is no longer than about twice the wire spacing. And accurate modeling with MININEC will require that the antenna be at least about 0.2 wavelength above ground. If your model satisfies these requirements, the results should be quite accurate.

For more information about MININEC limitations, see "Mininec: The Other Edge of the Sword", QST, Feb. 1991.

5767. Mil Sat Antennas etc.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-28 03:14:12 UTC
From: The Freak <scanner_freakSPAM@hotmail.com>
Message-ID: <d79l9.9725$Sr6.321290@ozemail.com.au>
Source record: 134008

I know this isn't the Scanner NG, however my question was posed to those NGs that are supposed to house the subject matter experts, however, no one has replied. I am hoping that you, the Amateur Radio experts can answer my questions.

With all the activity building up in the Gulf I am looking for some expert advice and someone to share the secrets regarding how to scan Mil satellite and,
HF/VHF/UHF traffic using your typical all mode type scanners, such as the AOR type scanners and dedicated HF/VHF/UHF rigs. Here are a few questions regarding the topic that I'd love to have answered.

What type of antenna is best suited to receive the Mil Satellite transmissions?

Will a discone with a pre-amp suffice? if so, what type of pre-amp is best suited to scanner use?, baring in mind front-end overload and the like

What are the best frequencies to listen to during times of increased Military presence in the Gulf and Afghanistan region? Apparently the 260Mhz region is best for this!

Has anyone got a full freq list for the Airforce/Navy/Army/Marines and the like to cover the above modes, incl AM/FM/SSB transmissions

Has anyone got a how to home make (homebrew) a scanner antenna best suited to scanning Mil satellites in the 260Mhz area, if so may I have a copy of the plans or a link?

Any tips/hints comments regarding this subject are very much appreciated. Seems that there already has been an increase in traffic and has got to be the best indicator that things are hotting up Mil wise over there. So with this in mind, we the arm chair warriors would love to be able to listen to the
action, as it were. Although, I understand that some, if not all, transmissions that are sensitive in nature will be encrypted, I know from past experience that human error has caused the odd message or two to be transmitted 'in the clear', these are the transmissions I hope to capture and get excited over...

To give you a little insight into the equipment I am currently using, I have an Alinco DR605T, a Yaesu FT757GX2, AOR8000 all mode H/H, a Yaesu FT290R and a Radio Shack 2006. These radios are for receive only and as I am currently studying for my Licence hope that sometime soon I will be able to use them to transmit. I am an avid radio buff, and love everything from packet, HF, CW and just about every mode of radio including Spread Spectrum, but for the life of me, have had no joy with satellite reception. Can someone please

assist or point me in the right direction!

My comments...
As far as satellite comms I think you would be very unique to find
anything receiveable and unencrypted.
260 MHz range local comms are not going to be relayed via satellite (to
my knowledge)and are most likely inaccessible at your QTH in VK.
Your best bet for eavesdropping would be the standard Air Force SW freqs
like 11.175 where insensitive traffic is always active and you can get a
'feel' of the activity. There's about a half dozen freqs like 11.175 in
use around the world and they are readily found on the web.

Lest I get Wouff Hounged about divulging National Secrets, I feel
compelled to add that the ever increasing tensions in the Middle East
are not a game where a hapless SWL is somehow going to be privy to the
odd unencrypted message that the rest of the World doesn't know about.
Your inference about a "buildup in the gulf" belies your sources of
information. Sallying about with random pieces of out of context data
is just as bad as divulging real data.
I wouldn't want to see a single serviceman die because some 'Freak
monitor station' posted info on the internet about what he had heard.
I hope you will take that into account. Three thousand dead in an
attack on your country might lend you to think twice.

-BM

wow, 2m. i'm curious. what's the diameter of this rope that raises
what weight that high in approx what mph wind?

sheave and block. good terms. we never say pulley in CATV. roller. 90
deg and 45 deg block. sheave is reserevd for those who know more than
the average cable dog.

it would be nice if you could thread your 2 or 3mm wire inside that
hollow braid poly line. leave enough rope on the ends for tying off.
too bad it doesn't come with a pull string inside. the 1/4" stuff is
good to IIRC 150 lbs. haven't really weather tested it though.

> That is what OPSEC is for.

I'd have to be a lot more net savvy than you to know what your laconic acronym OPSEC is. A Google search reveals another wanky security scheme and if that is your answer to protecting servicemen, well then you might as well bugger off lest you become a buggeree of the "savage arab hordes" which seems to be your inclination given your treatment of my comment.
Geezus, get off the freaking internet if it does that to you.

Message-ID: <Rgbl9.9744$Sr6.321786@ozemail.com.au>
Source record: 134014

Gentlemen please, I just asked a question regarding reception of Mil Sat transmissions. The basis of my comments are merely assumptions made by things called indicators, nothing new. There is increased radio comms traffic and in relation to OPSEC these indicators or lack thereof are how we gauge how well we are protecting operations and exercises and the like. Now I am not wishing to get political here and I don't want to offer comments with respect to how people died and the like. I wish to get back onto the subject of Mil Comms.

Secondly Sir, I tend to disagree with your assumption that nothing may be heard on that or any other UHF frequency in VK. There are others successfully receiving transmissions here in VK, my post was to gauge the experts opinion on how best to construct antenna and the like.

Am I wrong here, let's not get emotive about things.

Sorry to have asked the question! If I knew that I would have this type of impact I wouldn't have bothered. Oh and by the way, I can asure you that the OPSEC concept is NOT 'wanky' as you so freely call it. OPSEC will save lives if conducted properly and I assure you that the US does it best!

All the warmest regards and condolences re your losses, can we now get back to the topic?

The Freak (downunder, Australia)

Mr. Freak,
I don't take issue with your enthusiasm to intercept the transmissions eminating from the Middle East, and don't call me Sir.
If there are others receiving 'the' transmissions in VK maybe they would be a better source for concise tips rather than from a nation that feels itself under siege. That may have a political slant but if there's guys in Perth who are logging satellite or 260 MHz stuff from the Middle East then so be it.
As far as the OPSEC whatever....I'd like to think that the US Mils are doing something beyond that although I could well be wrong about our capability.
I can't speak with any authority on the subject of how you can receive secret traffic in VK-land other than following the CNN vans around and see how they do it.
My closing point was that it IS an EMOTIVE subject and its impossible to arbitrarily exclude that as qualification to your question in such times as we are experiencing now.
Now if you speak Arabic or Farsi or whatever and would like to put your SW sleuthing talents to good work...

Mr Bill, I think you lost the thread somewhere along the line here, the guy was asking for general information regarding building an antenna irrespective of the purposes for which it would be used for, i didnt realise political issues were involved in such practises, maybe we should take a look at what political issues are involved in owning and using any type of amateur/radio equipment...

Hello Brian

> Well my local 'normal' B&Q does rod, tube, and strip in Al, brass, and
some
> composite material (plus others not so interesting to hams).

Any chance you could point me in the area of the store I should be looking?
I've been in the hardware area, generally nearby where the screws and nuts &
bolts are.

My experience is that your average B&Q employee responds with a grunt if
you're lucky, and then if you're really lucky points you vaguely to nowhere
because they really don't know. :-(

BTW, here's one of my creations, courtesy of B&Q
http://www.g6lvb.com/dayton_demo_2002.htm made of 4mm Al rod from B&Q. 70cm
RHCP yagi, 8+8 elements, tunes to better than 1.1:1 VSWR in the satellite
portion of 70cm, under 1.4:1 across the entire band. Plans at
http://www.clarc.org/Articles/uhf.htm. I can recommend these antennas if you
have a history of antenna failure like I do.

Hi Rich-- Go for it, Make it as big as possible and put it up as High as possible.. feed it with balanced line and it will work well on all bands. Mine is 520 long (or should I say around) and up 35 feet on average. It is the best all round antenna I have here. on 160 it will work more or less out to about 2000 miles at night Have wrked some dx with it.. on 80 and above it makes a good all round antenna.. on the higher bands say 20 and above you may also want a vertical or dipole to fill in the nulls in the radiation pattern.. there is a good discussion on Cebik's site about large Horizontal loops. take a look at that.

Well in my local store (Gillingham, Kent) it is right next to the items you
list, along with Al and mesh sheets.

I found the 6mm O/D Al tube pretty good and hard enough for my needs- I was
even able to tap it sucessfully for one experiment.
There are 2 tubes- a plain finish @ £1.46 a 1m length and an anodised finish
which is more expensive.

I think it is too hard not to be an alloy- for 'quick lashups' I sometimes
us Al welding rod- that is much softer.

>
> My experience is that your average B&Q employee responds with a grunt if

The older ones are OK but the real problem is the stock control- no concept
of ordering things that seem to be selling out but pack the floor space
with stuff that never seems to move until the next sale.

I'll have a look. I plan to build a 2m and 70cm handheld Yagi like the Arrow one- if I ever I get time for my own projects ;-)

Check out my download page for the 'BRAT Hunt DF antenna' - it has proved very popular and I've yet to have an adverse comment as regards its working.

Chirs

Normally an antenna such as this is cut to resonance for the 11 meter band. It may have loading coils for that freq and not work reliably on 6 meters.. If you want to try it id suggest a swr bridge and trying very low power first to see if the antenna will even present a correct load to the transmitter. The old saying nothing ventured nothing gained. MFJ makes some good antenna analyzers which would paint a good picture for you but they are not cheap.

I built a J antenna for 6 which worked quite well. Mechanically it was a challange but very cheap to build.

Best of luck in your venture.

Autek Research currently sells also aerial analysers. Generally cheaper than
MFJ. Some give more vectorial information than MFJ but don't extend to VHF.
At this frequency, it could be a better choice.

Please don't be so harsh with someone calling themselves 'Doc'; he very well may be a 'Doc' but in an unrelated field. For example, my neighbor is a medical doctor and very knowledgeable in his field; but now that he is interested in amateur radio, he is a great student though his knowledge is minimal in radio theory.

Most of we Ph.D. type doctors having specialized into a quite narrow field are undoubtedly expert in our field; however, I can speak for myself in readily admitting that the more I know the more I am impressed by how little I really know.

I was amazed how stupid my Dad was when I was in high school; now I am truly astonished at how intelligent and diplomatic he (and was!). I was just to inexperienced, or ego-centric, to know.

Tact and gentleness are not signs of weakness or lack of masculinity. They are signs of maturity.

Regards,
Bill, NI5F

Depends on the design of the antenna. For example, it might have a base loading coil that would not function properly on 6m. Using an antenna tuner might help but, in any case, you might have fun experimenting.

Trees wrote:
"What do you mean "input SWR" ?"

SWR is a function of mismatch. It is a useful expression though the transmission line may be short.

An antenna of the standing wave variety is a resonant system with distributed inductance, capacitance, and resistance. In resonant antennas, the feedpoint is a resistive load. Impedance is low when the antenna element is an odd number of quarter wavelengths. Impedance is high when the element is an even number of quarter wavelengths. In between resonant lengths, the antenna element is capacitive or inductive in addition to having a resistive component which also varies with frequency.

So, the bandwidth of an antenna may be defined by the frequency range over which it presents an acceptable impedance to the radio.

Antenna radiation pattern is a function of current distribution in an antenna and this varies with frequency. So, the bandwidth of an antenna may also be defined as the frequency range over which its pattern is acceptable.

Best regards, Richard Harrison, KB5WZI

Does anybody have any experiences they'd like to relate re. the Hy-gain 10-meter 3 el. Yagi, LJ-103BA. I just picked one up NIB at a great price and am curious. I'm considering the use of a Centaur or Radio Works 1:1 Yagi balun instead of the Hy-gain BN-86/BN-4000B balun(s). Thanks. :-)

That's probably because the 1/4 wave monopole only has a feedpoint Z of 35 + j0 ohms when used over a perfect ground plane. Loss resistance in the ground connection can easily reach 15 ohms.

I've heard of cases where a ham installed a vertical and got 1:1 SWR on certain freqs from Day 1. Then said ham installed a flock of radials, and complained because the SWR went up.

> Trim with a hacksaw.

That would be needed unless he wants a cloud warmer. If the CB ant is
a 1/4 ground plane, this would be a simple conversion. Just trim all
the elements to a 1/4 wave for 6m. If it's a 1/2 wave or 5/8 wave,
it's not so simple. Most 5/8's have a loading coil inside the tubing
at the base, and it's not easy to get to. And to make things worse,
most are using a grounded coil. This will cause real problems trying
to use it on 6m if you can't get to it to bypass, or reduce the number
of turns. IE: converting the 5/8 CB ant to a 5/8 6m antenna.
It might well be easier just to start from scratch with tubing and
make a 6m antenna. A 1/2 wave antenna , base fed, would be good for
6m, and fairly easy to build and match using a single turn loop and
cap. A 1/4 wave ground plane would be simple to make from scratch. If
you use a 1/2 or 5/8 cb antenna on 6m without trimming the radiator,
the antenna is way too tall, and will show mainly high angle
radiation. Will be the pits for 6m FM use. If SSB use is planned , I
would use a simple horizontal dipole. But a vertical is preferred for
FM use in most cases.

Pretty hard to do since the FT-100 firmware will not tune below 40 meters
with it in ATAS mode.

> I have heard there is a mod or tuner available
> to do this, but have found nothing on it. Any ideas?

> Scott
> N2WMD

I have used an LDG AT-11MP autotuner with the ATAS on 75 and 80 meters with
marginal results. I extended the ATAS to it's maximum, then took the FT-100
out of ATAS mode and into TUNER mode, then activated the LDG tuner. It will
tune well enough to keep the FT-100 happy , but there's not enough antenna
there to radiate very well at these frequencies...

My Kenwood TS-570S(G) tuned an old 11 meter vertical and all my initial 6 meter contacts were made with that. How much power was going out and what the radiation pattern is a mystery, but, when the "Magic Band" is open anything will work, or so it seems. Does this mean it works, yes, does it work well, no, but it was better than nothing at the time. Have since built a 5 element beam, needless to say it works much better.

I'm assuming it is a 1/4WL monopole with radials designed for 11m.
The problem with using it on 6m where it will be close to 1/2WL is
the feedpoint impedance which will be too high to use coax without
base matching. As someone else suggested, you can trim it to resonance
on 6m by cutting all the dimensions to a little more than half their
present length. Note that 27MHz x 2 = 54MHz.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-29 05:04:58 UTC
From: Dick Carroll <dixie@townsqr.com>
Message-ID: <3D95025B.1C18E992@townsqr.com>
Source record: 133957

Rich McMahon wrote:

> All
>
> With wire antennas when is it appropriate and necessary to use a
> balun.. I understand that basically its an impedance matching
> transformer.

I never would use a transformer type balun on a dipole antenna. A choke balun can be advisable. When the coaxial feedline is a halfwave or a multiple thereof, or something even close, the outer surface of the coax can become a third "leg" of your dipole. and can also change the resonant frequency of the basic dipole itself with the added length. In such cases it is very much advisable to use a "choke balun". If the coax feedline happens to be a quarterwave or multiple, or close to it, it will present a high impedance and should pose no such problem.

> Does it also isolate RF and keep it off the feed line and
> out of the shack..

A choke balun, which is no more than an RF choke which can consist of a few turns of coax wound into a "hank" and hung below the dipole feedpoint, can serve to decouple the coax outer shield surface and both prevent it from acting as a third element to the dipole, as above, and also keep RF out of the shack.

Transformer baluns are mostly more trouble than they are worth for a large portion of hams. Actually they are provide false sense of security since they raise your expectations. Sure, they can be made to work properly on a narrow range of frequencies with little hassle, but most hams don't want to be constrained to a narrow range of frequencies. Wideband baluns are special cases.

> Oh i'm using a G5RV full size and a differential T
> turner from MFJ..

If you want to use a balun to keep RF out of the shack, wind a dozen turns of coax into coil and place it just before the junction of the coax and the balanced line.

Source record: 133961

I want to use a QRP CW transceiver (7.000-7.060) having an SO-239 jack that expects a 50 ohm unbalanced antenna. I, however, will be using a resonant, balanced dipole and a 300 ohm twinlead feedline. And no tuner. I believe I will need a 6:1 balun.

I see a diagram for a 4:1 voltage balun in Fig. 36 of Chapter 26 of the ARRL Antenna Book. What makes this a 4:1 balun? Can it be adapted to 6:1? Are there any diagrams for a 6:1 balun? Does anyone sell a 6:1 balun for QRP backpacking? I see big ones on the web, but no little ones. How come almost of the references to 6:1 and 9:1 baluns are in German? Is RF different in Germany?

>Anyone know how well they work?

They work well. I have the one sold by CCRadio, the Select-a-tenna. If there is just the tiniest sliver of signal present, the loop will amplify it quite a bit.

How practical the loop is, is something else. If you're in a large city where there is an AM station every few clicks of the dial, they will interfere with trying to pull in faint signals, unless the signals are totally in the clear.

I built one of the larger loops for BCB DXing. Actually its a bit
medium-sized because they can really be unwieldy in the shack. Mine is
18" on a side.
It works quite well and of course is very directional which was the
original intent. A random-wire outdoors will certainly catch more RF
out of the air but having the directional characteristic is a great
advantage for DXing.
No pre-amp involved...in fact the tuning Q is high enough to provide a
fair amount of rejection to nearby frequencies.
This page has all the scoop, including a great calculator.

Nope, you won't. Make the twinlead 1/2WL on 40m (~63 ft) and the
impedance seen by the transmitter will be close to the same as the
antenna feedpoint impedance. Your SWR will be close to 1:1 requiring
no tuner and all you will need is a 1:1 balun/choke.

Ken, you don't need a 6:1 or 4:1 balun. You are confusing the
characteristic impedance of the twinlead with the impedance
that will be seen by the transmitter. When feeding a resonant
dipole with 300 ohm twinlead, the transmitter will NEVER see
300 ohms. If it was a resonant folded dipole, the transmitter
would see about 300 ohms and you would need a 6:1 balun. You're
not talking about a folded dipole are you?

Source record: 133869

It's not a good idea to insult your radials.

They invariably will get even with you, by popping their nose up just as you pass over them with the rotary mower and grab onto it.

Then the mower takes off across the yard, ALWAYS in the direction of the antenna and often smashes right into it damaging a coil somewhere.

So they can hear you insult them!

All of my radials have the insulation still on them, so it may act a little like earmuffs to them, and they don't always hear the insults<G>

If you speak about your cellphone antenna, this wrap is just a dielectric wire for stopping the modal sound vibration of the antenna due to wind when you drive. This has no effect on the wave propagation.

If your loop has an active preamp, that may be the reason for the strong signal problems. I have a passive 16 inch loop, and it's the opposite. It's a much better antenna for city use than my wire antennas. It's so sharp in tuning that any nearby local station will be attenutated quite a bit. If you can null the local station, and still hear the desired station, it's way better than my wire antenna as far as blocking locals. And here in Houston , we have a few local stations..MK

Yep. That can help. But I don't think my loss is that bad here. But we
have pretty conductive soil here.
>
> I've heard of cases where a ham installed a vertical and got 1:1 SWR on certain
> freqs from Day 1. Then said ham installed a flock of radials, and complained
> because the SWR went up.

Thats no problem though usually. Even with 35 + jo, the SWR is still
under 2:1. I think an inv L actually models even lower than 35 +j0
ohms due to being a short , top loaded vertical, but in the real
world, I've never needed a matching device for one. Mine is about
40-45 ft tall I think as far as the vertical section. But on 160m, I
can take a fairly high SWR without problems. At least as far as my
TS-830 or drake T4XB is concerned anyway. They can usually handle 3:1
or worse, and still be within loading range. But even my 706 is fine,
as long as I don't stray too far from my design freq, which is about
1.835 or so. My present version is tuned mainly for the lower end of
the band. I'd have to double check, but it's SWR is under 1.5 to 1
where resonate. If the SWR changes, and the bandwidth is reduced when
adding radials, at least you know you needed them , and they are doing
their job. The bandwidth can be used as an indicator of radial
saturation. Once you get to the point where adding radials produces
little change in bandwidth, you usually have enough for "gov" work.

Ken,

Assuming you are using a folded dipole, its actual impedance is closer to 250 rather than 300 ohms. A 4:1 balun will be just fine. If it is a straight, rather than folded dipole, why bother with the 300 ohm twin lead? Just use a 1:1 balun, or no balun and 50 or 75 ohm coax. If you use 75 ohm coax, an SWR meter will say your WSR is 1.5:1.
That's because it is calibrated for 50 ohms. The actual SWR will be near 1:1.

With QRP you are not going to be greatly concerned about RF in the shack; so, I would go with a conventional wire dipole, no balun, and RG59, RG8X, or RG58.

It's a passive loop, about 8-10 inches in diameter, and I bought it in the hopes that I could pick up some Houston stations from San Antonio, especially the sports talk shows on AM 610 and AM 950 in Houston, but AM stations in San Antonio are too close to those frequencies. Only thing I can get reliably from Houston is AM 740, and that comes in at night, mainly.

> that will be seen by the transmitter.
==========

Hello CAM,

- and from where does this and similar confusions arise ?

They arise from the ancient but still popular mis-conception the common or garden SWR meter, in its usual location immediately between transmitter and tuner, actually indicates an SWR anywhere on the transmitting site. Its name is a horribly misleading misnomer. We are are now in the 21st Century.

The meter's function is better described as a "Magnitude of Reflection Coefficient Relative to 50-ohms Indicator". But this implies all transmitters require a 50-ohm load resistance - which they don't. This is a far too long-winded title anyway.

Since it doesn't actually measure anything, on this Great ever-to-be-remembered Day of 29th September 2002, let it be announced that this undoubtedly indispensible instrument will henceforth be referred to as the TLI - the Transmitter Loading Indicator.

Unless someone can think of a better name before tomorrow. ;o)

How about marking the indicator face with green and red bands - good and bad ?

If you MUST have some numbers on it, mark the scale 0 to 9.

It can continue to serve the double purpose of TLI and S-meter (the other indispensible indicator) for transceivers.

Equipment manufacturers and handbook editors please force yourselves to consider.

Yours, Reg, G4FGQ

======================

It's very true if the bit about bandwidth is deleted. The time to stop
adding radials is when the TLI stops changing. Then add two more for luck.

Hi all,
I came in on this thread late but...
Has anyone out there tried the fishing line called Fireline? It is damn near invisible and can be found in, I think, 50lb test which is much thinner than regular mono or nylon. It is very slippery and tough. Would work for putting wires through trees with just about anything and probably would support wire for a long time. I also have used rope with screen door springs to tension and expand when the wire is under wind load. They work great. Another thing I have used is a few window weights attached to ropes and run through pulleys to tension and let the wire move. I never did like the idea of the window weights falling on some ones head though. (I am a safety director :<)

Bert,

I had a BN86 , on which the screws rusted shut after about 20 years. So, when I got a Hygain TH3MK4 a couple of years ago I replaced the BN 86 with a different brand (can't rermber which). Works great. Just get a balun that is meant to work with a BEAM. These have a bracket for fastening the balun to the boom. Either AES and/or HRO has these in their catalog. Note, the balun mounting instructions did not make sense for a Hygain beam, so I ignored them. From what I hear, a lot of baluns don't work right on 160; they should all work on 10m. I suspect the beam balun is more optimized for the 14 - 30 MHz range.

Hmmmm?

If a 1/4w vertical is approx 35 ohms at resonance and the vswr shows 1:1, 15 ohms is coming from somewhere, no? I had always thought that is from ground lossses. As you reduce ground losses, the vswr bandwidth will decrease, won't it? Is there some other variable that we aren't considering? Maybe I shouldn't go here, but if Q=Xl/R and R is increased, Q decreases and bandwidth increases, doesn't it? Maybe you can't apply the "Q" formula here, so please don't hammer me for it <grin>.

It seems to me the greater the part of a perfect 50 ohm match to an antenna that resistive losses play, the wider the vswr bandwidth, so I'm not sure why Reg says the part about "bandwidth" is wrong. I thought ground losses in a 1/4w vertical tended to "mask" the changing impedance of the antenna itself.

If this is all old wive's tales, someone please set me straight. I have always found that as ground losses are reduced, the vswr (and vswr bandwidth) both change. The resonant vswr increases and the 2:1 vswr bandwidth decreases. Is this generally true, nearly always true, or a complete myth? If it is a myth, what accounts for my actual measurements over the years? If it isn't always true, then what boundary conditions obtain at those times when it isn't true that:

With a 1/4w ground mounted vertical as ground losses are reduced vswr increases at resonance and 2:1 vswr bandwidth decreases. I think that is what Mark was saying, and I await an explanation that will prove him wrong.

I had one of it's big brothers a 204BA 4 el. Hy-Gain 20m beam up for
30 years, the thing boomed and had a nice F/B ratio. I'd do any
Hy-Gain HF single-bander in a wink. Baluns: Install a string of beads
on the coax at the feedpoint of the hairpin match and be done with it.
Run a search on "Bytemark" for info on the beads.

StarGazeer wrote:
"If SWR changes, and the bandwidth is reduced when adding radials, at least you know that you needed them, and they are doing their job."

The addition of radials usually reduces earth loss to some extent. Q is X / R or R /X , depending on series or parallel connection.

A standing-wave antenna is most often a series-resonant system. Reducing R by adding radials increases Q.

Bandwidth is inversely proportional to Q and StarGazer is correct in saying "bandwidth is reduced when adding radials".

The purpose of radials is to increase efficiency by lowering loss in the earth, unless the antenna is far from the earth.

SWR changes because antenna impedance is the sum of radiation resistance, loss resistance, and reactance if the antenna is not resonant. SWR is an indication of mismatch between the antenna and the feedline. Changing the antenna impedance by reducing its loss also changes SWR.

StarGazer is correct in assuming SWR changes when radials are added, but you may not "know you needed them" because the change may be so small that the effort isn`t justified.

Best regards, Richard Harrison, KB5WZI

> their job.
>
> Why is this true?

Because you have lowered the radiation resistance of the antenna system and moved it away (lower) from the feedpoint impedance of 50 ohms...now you have more of a mismatch. But you have less loss so the system will radiate better.

IOW if the vertical had 35 ohms and the poor ground 15, you would have had a lossy antenna system but one which would show a broader bandwidth and an SWR of 1:1.
So you have improved the ground plane, it has less resistance, say now 5 ohms for a system total of 40 ohms, and now the SWR no longer has a 1:1 match. It shows worse SWR but radiates better because you're losing less RF as heat into the ground. And it will also be narrower banded.
Of course the world won't end if you go on the air with the lossy system, and you will make plenty of contacts. And unless your problem is fairly significant it wouldn't be easy for most hams to notice the difference.

Dick

> k5qwg

Hummm, I listen the other way around quite a bit. "San Antonio from Houston". Haven't had much trouble on this end. I can be only 10kc off from 740, and hear just fine on 750 if I use a narrow filter. A little crud on a wide filter...But it's quite usable. 20 kc away, I can use the wide filter. It's a lot better than using my wire antennas. I can listen to 590 with a wide filter, and no crud at all from 610. 740 is 50kw I'm pretty sure, and semi clear channel I think. It's fairly stout. My loop is a 16 inch circle. I built it on a junked humidifier blower housing, which is plastic. It's about 12 turns, and with the cap I have, tunes from 500-2000 kc. At the moment, I'm using a 2 turn coupling loop to fead it. But it worked quite well even directly fed. I think the balance is slightly better with the coupling loop though. It's on a stand with a short appx 2 ft tall mast and rotates. Almost looks like some kind of microwave dish or something with the housing it's on. Many local stations in the daytime, I can almost totally null out if needed. The null is very sharp, so the chances of nulling the desired station is fairly slim. It's usually in another direction. But say in the case with 740 and listening on 750, which I just tried with the 706, I didn't even bother nulling 740. I usually can't get a total null at night, although I can knock em down a good bit.

I'd like to hear this too. I sure don't want to be spreading old wives
around. But what I've seen here with my antennas doesn't jive with his
statement that this is not true. I've also seen this phenomenon quoted
many times in books, so I'm not the first to say that. Wide bandwidth
doesn't always equate to a lossy antenna. But as far as ground mounted
or even elevated monopoles, "ground planes" , and the number of
radials used over a less than optimum ground, I think it does. If you
are over seawater, adding radials shouldn't change a thing as far as
bandwidth as they were not needed. It's like laying radials over a
solid copper plate. Silly... But radials over rocky ground I bet do
make a difference according to the number of them. They seem to make a
difference here over my fairly decent ground. "a reduction of
bandwidth or a higher Q with more radials"

==========

There's no argument about this characteristic of a simple LCR tuned circuit.

But in practice, how is the operation of a 'tuned-up' transmitter affected by this change in Q? And how is adjusting knobs affected? Where does SWR come into the act?

And would the operator be aware of the change in resistance of the antenna+ground other than it being necessary to readjust the tuner for SWR=1:1? He also does this if inductance changes or if capacitance changes. He has no means of distinguishing which is which.

So what do you mean by bandwidth in connection with operating a radio transmitter. Can it be measured ?

<snip)

That's really good news. I was afraid I'd been hanging around to many aged
married females.

>
>
> So what do you mean by bandwidth in connection with operating a radio
> transmitter. Can it be measured ?

Not only can it be measured...it has a very practical effect. If the antenna
system is lossy, you don't have to re-adjust your tuner as much. You can run
all over the band without touching the tuner. It has "wide vswr bandwidth",
or if you prefer, "impedance bandwidth". The TX sees a fairly stable load
over a wider freq range when the system being discussed is lossy.

I have never put up an antenna that I didn't measure the following for:

1. Freq of lowest VSWR.
2. The two freq (above and below resonance) where the vswr has risen to 2:1
vswr.

In a ground mounted 1/4 wave vertical, measurement 1 is a good indicator of
efficiency, esp if adding/subtracting radials.

In a ground mounted 1/4 wave vertical, measurement 2 is a clear indicator of
efficiency, esp if adding/subtracting radials.

Further, repeated measures over long periods of time or after significant
weather events are good indicators of other variables.

Example:

If you have a very wet spring following your dry fall install of the antenna
and you find that your vswr at the low point has gone up and the vswr
bandwidth has gone down, you may be seeing the effect of improved ground
losses. If so, it's time for more radials!

I have made graphs of every antenna I have in the air and saved to my hard disk. Every graph has the date, the freq of lowest vswr and the 2:1 vswr bandwidth. I bet I'm not unusual in this respect. It doesn't matter what the vswr meter is measuring. What matters is how far does it deviate from 50/37.5 ideal. Any 1/4w ground mounted HF vertical that shows 50 ohms or a 1:1 vswr without any matching network has problems, period and they are most certainly ground losses. Nothing more than a cheap vswr meter and your tx is required to figure this out and to fix it.

I'm now convinced that Reg was just trying to pull our chain (and to some extent, he succeeded).

73,

hasan, N0AN

Ken, KC2JDY wrote:
"---will be using a resonant, balanced dipole and a 300-ohm twinlead feedline."

Ken also wrote: "What makes this (Fig 36) a 4:1 balun?"

This is a centertapped choke or a 2:1 turns ratio autotransformer. The impedance ratio is the turns ratio squared or 4:1.

For a 6:1 impedance ratio to match 300 ohms to 50 ohms requires a turns ratio of about 2.5:1.

The pictorial in Fig 26 shows 5 bifilar turns. About 12 turns would produce 300 ohms impedance when using 5 turns for 50 ohms impedance. You could tap a 12-turn coil on the core at 5 turns or wind separate coils on the core. Separate coils are likely to improve balance but may have a little more loss. In an autotransformer, primary and secondary currents flow in opposite directions in the shared coil turns. Another coupling problem is reduced permeability with core materials for higher frequencies.

Were a folded dipole made osf the same 300-ohm twinlead used for the feedline, by shorting the ends od a 1/2-wave section and breaking one side in its middle to attach the feedline, the antenna could match the feedline. For this to happen, the dipole would need to be erected about 50 feet above the earth (1/2-wave).

A single-wire dipole has the same radiation as a folded dipole. Its drivepoint impedance is about 72 ohms in free space or at 1/2-wave elevation when the usual wire is used for its construction.

It can often be fed directly from an unbalanced
50-ohm coax at the usual too-low height used by amateurs and a fair match is obtained. If the radio has a good ground and the feedline is around 1/4 or 3/4-wavelength, 25 or 75 feet in this case, a high impedance is presented to the antenna by the outside of the coax and radiation from the coax should not be a problem.

Best regards, Richard Harrison, KB5WZI

From the ARRL Antenna Book, 15th edition.

SWR bandwidth = 100% x (F(high) - F(1ow))/F(center)

Any SWR can be chosen but 2:1 is common in ham
radio.

I wrote:
"Its drivepoint impedance is about 72 ohms in free space or at 1/2-wave elevation when the usual wire is used for its construction."

I was perhaps remiss not to say that the lowest elevation to find free space impedance in an ordinary dipole is about 1/4-wave. These are cloud warmers.

They also complain that the bandwidth of the antenna decreased as well.
Less loss means higher Q. Of course, my dummy load has a wider
bandwidth by far than any of my "other" antennas.

"You could tap a 12-turn coil on the core at 5 turns---."

I would center-tap the 12-turn coil for a ground connection and place the 50-ohm connection at one turn from either end of the coil. End-to-end, the center-tapped coil would present about 300 ohms if loaded with 50 ohms across 5 turns.

It's prolly good for parts, but not without modification. I got one comprising a 1/2 wave aliminum pipe stuffed into a 2' f'glass insulator with a coax matching section. With the matching section removed and a short piece of tubing added it became a good 1/4 vertical on 20m. You otta get two or more 6m 1/4 sections with which you could make a horizontal dipole or a 2-element beam. Never turn down junk!

Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.antenna

Hello all,

I thought I would see if anyone else has successfully interfaced the Kenwood AT-250 automatic antenna tuner with an ICOM IC-735 transceiver. I would think this is has been done and would prefer not to re-invent the wheel if I don't have to. I'm not particularly interested in the automatic band selection feature as the IC-735 and the Kenwood methods of relaying this information to the tuner are quite different.

If you've done this, I would appreciate the appropriate pin out information from the IC-735 accessory port to the AT-250 port. Many thanks in advance.

73,

Rick, KG6RJ

Took one down to Dog Beach (Near San Diego) to QSL Oz without QRMing my neighbors too many years ago. Left the YL holding up the mast while I pulled a car out of the sand with the RV. Naturally, a crowd formed wondering what she was doing. "Talking to Australia, of course .... CQ Oz! CQ Oz!" They merely said "Oh" and wandered off ... such behavior being normal in/around OB.

I will add one comment.
Although I ran the tuner into several different "Balanced" loads, I ALWAYS grounded the ground terminal. No point in letting stray RF toast the CPU in the tuner. If the antenna is not designed to work against ground, there should be no ground currents to upset the balance.

I live in a rural area and there is one television station
that I would like to get but it just barely comes in with
my current setup (broadband TV antenna with rotor,
pre-amp, distribution system). I am interested in building
a separate antenna to improve reception of that specific
station. Anybody got any good links on how to do
such a thing? What type of antenna should I try - dipole,
folded dipole, Yagi, . . . ? Does SWR matter in a receive
only antenna? Any insight would be helpful. JELo

Check this page for some examples.
http://starkelectronic.com/winp12.htm
It will be difficult to build anything with substantially more gain than the antenna you have now and even these single channel yagis won't offer more than a couple db extra gain than a big broadband antenna.
What channel number and how far away is it? Maybe struggling for more height is the best answer.
And of course the obvious caveat would be to first check and make sure everything about your existing system is working as well as it should.
If the channel of interest is just 'barely visible' you'll need to snatch about 20db more signal out of the air somehow to get a 'snowy but watchable' picture.

Why isn't this solution used more in practice? Are transformers made
from air-core coils a lot lossier than 4:1 baluns? Are ordinary
transformers made using toroids a lot lossier than 4:1 baluns?

Source record: 133823

If you are now using a multi-element wideband antenna it probably has more gain on the channel you want than you will get with any kind of single dipole. You might try a single channel yagi if you can find one with more gain on your desired channel than what you already have.

SWR on the feedline from the antenna probably is less important than the signal loss in the line. Your preamplifier probably more than compensates for both. Note that the noise figure of most modern TV sets is quite good, and sometimes using preamps ahead of them can actually produce a noisier picture than without them. The signal level may be higher out of the preamp, but noise is added also.

Antenna height is important. But if you are quite distant from the TV station, and/or you have hills/mountains or just earth curvature in the way, you may already be getting the best picture practical.

Why not build a real 6 meter antenna? A 4 element 6 meter quad can be built from PVC and wire very easily for around $10, and will perform much better than a converted 11 meter vertical.

As far as that goes, a 6 meter vertical dipole can be built from the same materials for even less...

I will have to try and dig up the specs on what I
currently have and figure out where I stand.

> SWR on the feedline from the antenna probably is
> less important than the signal loss in the line.
When I rewired the (new) place a while back, I used
all RG-6 cable but I should check the antenna feed line.

> Your preamplifier probably more than compensates
> for both. Note that the noise figure of most modern

Good point. Out here the signal strength varies considerably.
I initially pieced together my set up at another residence with
different end equipment then dissassembled it and re-installed
at the new residence. I should probably backup and see what
of the pieces are really needed at the new place. When I first
put things together, of the six available retransmitted TV
stations, three could be picked up fairly easily without the
pre-amp, two could be gotten with it and one needed more
help even with the pre-amp.

> Antenna height is important. But if you are quite distant
> from the TV station, and/or you have hills/mountains or
> just earth curvature in the way, you may already be getting

I do happen to live in the foothills of a mountainous area
in Wyoming. I am guessing the clean stations are the ones
coming from the transmitting towers up on the mountain face
while the difficult stations are coming off the towers in the
rolling hills east and far north of town.

Thanks for the info, certainly gave me some things to
think about , JELo

The guy asking was being "given" a CB antenna and wanted to try to use it for 6 meters. Maybe his funds are limited or "maybe" he wanted to "experiment". After all, that is what Ham Radio is all about! Anyone can go "buy" an antenna.
As for the rest of the replies, they were merely - as mine, an opinion of how he should/could proceed using that particular antenna. That is the extent of the thread as "I" have seen.....

what i do is double click the message and read it in mailwasher if
i'm not sure. then i delete or bounce it. blouncing it, IIRC, puts
the sender on the blacklist. after getting rid of the crap, "Process
Mail", i download the rest into my reader.

you can also set mail washer to start your email app after
processing. with mine "PegasusMail" i have to find a command line
argument because calling the app with it's exe name alone opens a new
mail message.

but i guess that's what you mean. IIRC you need to set OE to download
mail automatically or find a command line argument that does that.

use a piece of pvc so the weight's inside. don't forget drain holes
or something.

fishing line would be hard to coil and keep neat. i like the 1/4 in
hollow braid poly. stretch it between 2 trees, pull it at midpoint,
tighten it, repeat, leave overnight. that gets the memory out of it.
now you can coil it up. the CATV eye nut is small and heavy and goes
through trees. i can hit a beer can at 25 feet or better with it. use
one of those dog snaps that open outward and don't snag branches as
much. the hollow braid stuff is cool because you can stick the end
back through the rope to make an eye without having to braid. it even
comes in a bag with a polastic i forget what it's called to help
thread it.

5892. What gauge wire for Windom?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-09-30 21:04:55 UTC
From: Max <ve3tmt@yahoo.ca>
Message-ID: <t03m9.4404$Kg4.416280@news20.bellglobal.com>
Source record: 133833

Some diagrams I see say 10 ga. other use 12 ga. I have some 10 ga. here
but it looks awfully heavy. The antenna will be used for field day use.
Can I get away with 14 gauge? Maximum power to antenna will be 100W.

Thanks,

Max

You can use this link to find out where the stations are located.
http://www.radiostation.com/kodis/

Fully ACK,but playing coy with physics ain't ham radio too,and that's what
the guy wants to do.Of course,everybody can tune any antenna to (almost) any
frequency....

Hi Max and all,
The Size will matter little except for strength.. #14 should work
well for the standard windom of about 136 feet long or so. If it's
for 160 that's 200 feet plus go with the 12 ga.

3 Singer model NM-25t EMI/RFI recivers for sale. Frequency range of
150Khz to 32Mhz. Detectors include field intensity and Quasi-peak.
It can be run off of AC or internal batteries. 127db dynamic range.
Will be sent calibrated and certified. All three are in extremely
nice pyshical shape. Buyer pays actual shipping charges. Asking
$1500.00 each.

Thank you.

CAM, W5DXP wrote:
"Why isn`t this solution (transformer) used more in practice? Are ordinary transformers using toroids a lot lossier than 4:1 baluns?"

My speculation is that an ordinary transformer is no lossier than a 4:1 balun. Loss has to come from the core material or the copper coils wound around that core. Some losses are functions of frequency and some are functions of power handled by the transformer and these should be about the same regardless the transformer application. This was for a QRP application so we won`t worry about core saturation. The turns per volt if good enough for the baluns in the example should serve as well for a slightly different ratio. We really haven`t increased current in the primary.

The original questioner referred to Fig 36 on page 26-25 of the 19th edition of the "ARRL Antenna Book". The difference in a 2:1 turns ratio and a 2.5:1 turns ratio only means adding one turn on either side of the center-tapped coil in figure 36. As 1/2 the coil is the 5-turn primary in the balun, and 5 turns of the 6-turn coil on one side of the center-tap is proposed as the primary for the 2.5:1 turns ratio transformer, not much has changed.

Power flow should be the same. Copper and iron losses should be about the same. A slight difference in losses results from a transformation ratio other than 1:1 in an autotransformer, but at the levels involved, I doubt that it`s significant. I haven`t seen many 1:1 autotransformers, but that doesn`t mean they wouldn`t be useful.

I seem to recall an air core r-f transformer problem caused by coupling decline in longer coils. This may be a cause for Q decline and the reason an optimum solenoid is kept fairly short. Is it no longer than 2x the diameter? I forget. But I believe it is a reason coils get link coupled in their mid-sections instead of at their ends.

Coils are not my speciality. Better gualified people might comment on the disuse of air core r-f transformers. The toroids have better permeability and coupling and this must be the reason they are used in baluns.

Best regards, Richard Harrison, KB5WZI

Wow! I haven't seen one of these since the 70's.
As I remember these were actually made by Stoddard.
